992. **Abdur-Rashid, Kamaluddin, Tara P. Dasgupta, Nicholas J. Blundell, John Burgess, and Duncan N. Drasdo.** "Solvation of Inorganic Complexes: Transfer Chemical Potentials for Mono- and Bi-Nuclear Cobalt (III) Complexes to Methanol + Water Mixtures." Transition Metal Chemistry 30 (2005): 176-84. **Refereed**

Solubilities in MeOH-H₂O mixtures at 298.2 K are reported for a number of salts of mono- and bi-nuclear cobalt (III) complexes. From these solubilities and published single ion transfer chemical potentials, on the TPTB (Ph₄P⁺ = BPh₄) assumption, transfer chemical potentials have been derived for these mono- and bi-nuclear cobalt (III) complexes. The results and trends are discussed in relation to those for other complexes and ions in these binary aqueous solvent mixtures.

993. **Anderson, Chadwick I., Helen M. Jacobs, and Williams F. Reynolds.** "Indole Alkaloids From Psychotria Corymbosa." [Abstract]. Proceedings of the Sixth Conference, Faculty of Pure and Applied Sciences: Kingston, Jamaica: Faculty of Pure and Applied Sciences, University of the West Indies, 2003. 33.

994. **Antao, Sytle M., Willem H. Mulder, Ishmael Hassan, Wilson A. Crichton, and John B. Parise.** "Cation Disorder in Dolomite, CaMg(CO₃)₂, and Its Influence on the Aragonite + Magnesite ↔ Dolomite Reaction Boundary." American Mineralogist 89.7 (2004): 1142-47. **Refereed**

The structure of dolomite, CaMg(CO₃)₂, was determined from 298 to 1466 K at a constant pressure of about 3 GPa using in situ synchrotron X-ray diffraction data to investigate the state of disorder. An order parameter s , defined as $2x_{Ca} - 1$, varies from $s = 1$ (where $x_{Ca} = 1$) for a completely ordered dolomite to $s = 0$ (where $x_{Ca} = 0.5$) for a completely disordered dolomite. On heating, there is no measured change in s until the temperature is high enough to cause exchange of Ca²⁺ and Mg²⁺ cations. Significant disorder began to occur at about 1234 K [$s = 0.83(1)$] and increases along a smooth pathway to $T = 1466$ K [$s = 0.12(5)$]. The R3 ↔ R3c transition in dolomite is described by a modified Bragg-Williams thermodynamic model with the following molar free energy of disorder, $G_d(T, s) = RT_c [1 - s^2 + \frac{1}{2}a(s^4 - 1) - (T/T_c) \{2 \ln 2 - (1+s) \ln(1+s) - (1-s) \ln(1-s)\}]$. Using $T_c = 1466$ K and $a = -0.29$, this model provides an excellent agreement with experimental data. Moreover, the maximum enthalpy of disorder, $H_d(s=0) = RT_c(1 - \frac{1}{2}a) \sim 14$ kJ/mol, agrees with published calorimetric data. A thermodynamic description of the aragonite + magnesite ↔ dolomite reaction boundary is also presented and it reproduces the main qualitative features correctly.

995. **Aquart, Danielle V., and Tara P. Dasgupta.** "Dynamics of Interaction of Vitamin C With Some Potent Nitrovasodilators, S-Nitroso-N-Acetyl-D,L-Penicillamine (SNAP) and S-Nitrosocaptopril (SNOCap), in Aqueous Solution." Biophysical Chemistry 107 (2004): 117-31. **Refereed**

The reductive decomposition of both SNAP and SNOCap by ascorbate in aqueous solution (in the presence of EDTA) was thoroughly investigated. Nitric oxide (NO) release from the reaction occurs in an ascorbate concentration and pH dependent manner. Rates and hence NO release increased drastically with increasing pH, signifying that the most highly ionized form of ascorbate is the more reactive species. The experiments were monitored spectrophotometrically, and second-order rate constants calculated at 37 °C for the reduction of SNAP are

$k_b = 9.81 \pm 1.39 \times 10^{-3} \text{ M}^{-1} \text{ s}^{-1}$ and $k_c = 662 \pm 38 \text{ M}^{-1} \text{ s}^{-1}$ and for SNOCap are $k_b = 2.57 \pm 1.29 \times 10^{-2} \text{ M}^{-1} \text{ s}^{-1}$ and $k_c = 49.7 \pm 1.3 \text{ M}^{-1} \text{ s}^{-1}$. k_b and k_c are the second-order rate constants via the ascorbate monoanion (HA^-) and dianion (A^{2-}) pathways, respectively. Activation parameters were also calculated and are $\Delta H^\ddagger_b = 93 \pm 7 \text{ kJ mol}^{-1}$, $\Delta S^\ddagger_b = 15 \pm 2 \text{ J K}^{-1} \text{ mol}^{-1}$ and $\Delta H^\ddagger_c = 51 \pm 5 \text{ kJ mol}^{-1}$, $\Delta S^\ddagger_c = -28 \pm 3 \text{ J K}^{-1} \text{ mol}^{-1}$ with respect to the reactions involving SNAP.

Those for the reaction between SNOCap and ascorbate were calculated to be $\Delta H^\ddagger_b = 63 \pm 11 \text{ kJ mol}^{-1}$, $\Delta S^\ddagger_b = -71 \pm 20 \text{ J K}^{-1} \text{ mol}^{-1}$ and $\Delta H^\ddagger_c = 103 \pm 7 \text{ kJ mol}^{-1}$, $\Delta S^\ddagger_c = 118 \pm 8 \text{ J K}^{-1} \text{ mol}^{-1}$. The effect of $\text{Cu}^{2+}/\text{Cu}^+$ ions on the reductive decompositions of these S-nitrosothiols was also investigated in absence of EDTA. SNOCap exhibits relatively high stability at near physiological conditions (37°C and $\text{pH } 7.55$) even in the presence of micromolar concentrations of Cu^+ , with decomposition rate constant being $0.011 \text{ M}^{-1} \text{ s}^{-1}$ in comparison to SNAP which is known to be more susceptible to catalytic decomposition by Cu^+ (second-order rate constant of $20 \text{ M}^{-1} \text{ s}^{-1}$ at $\text{pH } 7.4$ and 25°C). It was also observed that the reductive decomposition of SNAP is not catalyzed by alkali metal ions. However, there was an increase in rate as the ionic strength increases from 0.2 to 0.5 mol dm^{-3} NaCl.

996. —. "The Reaction of S-Nitroso-N-Acetyl-D, L-Penicillamine (SNAP) With the Angiotensin Converting Enzyme Inhibitor, Captopril—Mechanism of Transnitrosation." Organic Biomolecular Chemistry 3.9 (2005): 1640-46. **Refereed**

Kinetic studies involving the use of both stopped-flow and diode array spectrophotometers, show that the reaction between SNAP and captopril in the presence of the metal ion sequestering agent, EDTA, occurs in two well-defined stages. The first stage is a fast reaction while the second stage is slow. The first stage has been postulated to be transnitrosation, and the second stage involves the decay of the newly formed RSNO to effect nitric oxide (NO) release. Both stages are found to be dependent on captopril and H^+ concentration. The rates of the transnitrosation increased drastically with increasing pH in the first stage, signifying that the deprotonated form of captopril is the more reactive species. In the case of the second stage the variation in pH showed an increase in rate up to $\text{pH } 8$ after which the rate remained unchanged. Both stages were clearly distinguishable and easily monitored separately. Transnitrosation is a reversible reaction with the tendency for the equilibrium to break down at high thiol concentration. Second-order rate constants were calculated based on the following derived expressions:

$-\text{d}[\text{SNAP}]/\text{d}t = k_f \left(\frac{K_{\text{SHCapSH}} [\text{CapSH}]_t}{K_{\text{SHCapSH}} + [\text{H}^+]} \right) [\text{SNAP}]$. k_f is the second-order rate constant for the forward reaction of the reversible transnitrosation process. At 37°C , $k_f = 785 \pm 14 \text{ M}^{-1} \text{ s}^{-1}$, activation parameters $\Delta H_f^\ddagger = 49 \pm 2 \text{ kJ mol}^{-1}$. $\Delta S_f^\ddagger = -32 \pm 2 \text{ J K}^{-1} \text{ mol}^{-1}$. The activation parameters demonstrate the associative nature of the transnitrosation mechanism. The second stage has been found to be very complex, as a variety of nitrogen products form as predicted before. However, the following expression was derived from the initial kinetic data: $\text{rate} = k_1 K [\text{SNOCap}] [\text{Cap S}] / (K [\text{Cap S}] + 1)$ to give $k_1 = 13.3 \pm 0.4 \times 10^3 \text{ s}^{-1}$ and $K = 5.59 \pm 0.53 \times 10^1 \text{ M}^{-1}$ at 37°C , where k_1 is the first-order rate constant for the decay of the intermediate formed during the reaction between SNOCap and the remaining excess CapSH present at the end of the first stage reaction. Activation parameters are $\Delta H_t^\ddagger = 37 \pm 1 \text{ kJ mol}^{-1}$, $\Delta S_t^\ddagger = -181 \pm 44 \text{ J K}^{-1} \text{ mol}^{-1}$.

997. **Bakir, Mohammed A.** “Optical, Electrochemical and Structural Studies on the First Rhenium Compound of Di-2-Pyridylketonephenylhydrazone (Dpkphh), *Fac-Re(CO)₃(Dpkphh)Cl* .”

Inorganica Chimica Acta 332.1 (2002): 1-6. **Refereed**

fac-Re(CO)₃(dpkphh)Cl isolated from the reaction between $\text{Re(CO)}_5\text{Cl}$ and dpkphh in refluxing toluene exhibits rich physico-chemical properties. Spectroscopic measurements on *fac-Re(CO)₃(dpkphh)Cl* revealed strong solvent dependence as manifested by the high sensitivity of its ^1H NMR and electronic absorption spectra to solvent variation. Electrochemical measurements on *fac-Re(CO)₃(dpkphh)Cl* in CH_2Cl_2 show irreversible/quasi-reversible redox processes pointing to electrochemical transformation(s) following electronic-transfer(s). Crystals of *fac-Re(CO)₃(dpkphh)Cl*· CH_3CN obtained from an acetonitrile solution of *fac-Re(CO)₃(dpkphh)Cl* are chiral and structural studies show racemic twins of *fac-Re(CO)₃(dpkphh)Cl*· CH_3CN with *fac-Re(CO)₃(dpkphh)Cl* molecules in distorted octahedral geometry. The molecules pack shows stacks of well separated strands of *fac-Re(CO)₃(dpkphh)Cl*· CH_3CN in double helix formation with a network of hydrogen bonds that include solvent–solute and solute–solute interactions. The interlocked helical structure of *fac-Re(CO)₃(dpkphh)Cl*· CH_3CN and weak bond energies of the non-covalent interactions may account for the optical behavior of *fac-Re(CO)₃(dpkphh)Cl*· CH_3CN as any slight interaction between this system (*fac-Re(CO)₃(dpkphh)Cl* and surrounding solvent molecules) and its surroundings may disrupt the weak solvent–solute and solute–solute interactions.

998. **Bakir, Mohammed A., and O. Brown.** “Molecular Structure and Optosensing Behaviour of Di-2-Pyridyl Ketone Benzoylhydrazone in Nonaqueous Solvents.” *Journal of Molecular Structure* 609.1-3 (2002): 129-36. **Refereed**

Crystals of di-2-pyridyl ketone benzoylhydrazone (dpkbh) obtained from a dimethylsulfoxide (DMSO) solution of dpkbh are in the monoclinic space group, $P2_1/c$. Structural analysis reveals anti-parallel, non-planar, one-dimensional tapes of dpkbh with a network of intra- and intermolecular hydrogen bonds. Optical measurements on dpkbh in polar non-aqueous solvents revealed the presence of interlocked low-(α -) and high-(β -) energy intraligand charge-transfer electronic states may be due to $\text{dpk } \pi\text{-}\pi^*$ followed by dpk to benzoyl charge-transfer. The equilibrium distribution of the low-(α -) and high-(β -) energy electronic states is solvent dependent, controlled by the hydrogen bonding capacity of surrounding solvent molecules. The interplay between the α - and β -conformations of dpkbh allowed calculations of their extinction coefficients by forcing the equilibrium to shift to one conformation using chemical stimuli. In *N,N*-dimethylformamide (DMF), extinction coefficients of $45,000 \pm 2000$ and $15,000 \pm 2000$ $\text{M}^{-1} \text{cm}^{-1}$ were calculated for the α - and β -conformations of dpkbh at λ_{max} , respectively, when excess acid was added to a DMF solution of dpkbh. The weak bond energies of the hydrogen bonds, the reversibility and the sensitivity of the high- and low-energy electronic states to their surroundings in polar non-aqueous solvents allow for the use of this system as molecular sensor for a variety of stimuli that include metal ions, acids and bases. Metal ions in concentrations $< 10^{-7}$ M can be detected and determined using this system (dpkbh and surrounding solvent molecules).

999. —. “X-Ray Crystallographic and Optosensing Studies of Di-2-Pyridyl Ketone *p*-Nitrophenylhydrazone (Dpknph) in Dimethylsulfoxide (DMSO).” *Journal of Molecular Structure* 641 (2002): 183-91. **Refereed**

Crystals of di-2-pyridyl ketone *p*-nitrophenylhydrazone (dpknph), obtained from a dmsol (dimethylsulfoxide) solution of dpknph, are in the monoclinic space group, $P2_1/n$. Structural analysis reveals non-coplanar pyridine rings and infinite one-dimensional chains of dpknph with a network of classic and non-classic hydrogen bonds. Optical measurements on dpknph in dmsol in the presence and absence of CdCl_2 and NaBH_4 gave extinction coefficients of $91,000 \pm 2000$ and $35,000 \pm 2000$ $\text{M}^{-1} \text{cm}^{-1}$ for the high and low energy electronic states of dpknph at 295 K. Thermo-

optical measurements on dpknph in dmsO established the reversible interconversion between the high and low energy electronic states of dpknph and allowed calculations of their thermodynamic activation parameters and gave changes in enthalpy (ΔH^ϕ) of $-49.05 \pm 1.25 \text{ kJ mol}^{-1}$, entropy (ΔS^ϕ) of $+0.16 \pm 0.04 \text{ kJ mol}^{-1}$ and free energy (ΔG^ϕ) of $-96.30 \pm 2.45 \text{ kJ mol}^{-1}$ at 295 K. Manipulation of the equilibrium distribution of the high and low energy electronic states of dpknph allowed for the use of the system as cation–anion and acid–base sensor. Basic anions such as BH_4^- and OH^- favor the low energy electronic state and electron deficient anions such as BF_4^- , metal ions and protons favor the high-energy electronic state. The reversible $\text{BH}_4^-/\text{BF}_4^-$ and OH^-/H^+ interconversion points to physical interactions between these species and dpknph and the use of dpknph as a spectrophotometric sensor for a variety of physical and chemical stimuli. Metal ions in concentrations as low as $1.00 \times 10^{-7} \text{ M}$ can be detected and determined using dpknph in dmsO.

1000. **Bakir, Mohammed A., S. A. Clarke, Ishmael Hassan, Lancashire Robert J., and Marvadeen A. Singh-Wilmot.** “Trans-Bis(Glycinato-Kappa N-2,O)Copper(II) 4-Bromophenol Solvate .” *Acta Crystallographica Section E-Structure Reports Online* 60 .Part 6 (2004): M868-M870 .**Refereed**

The title compound, trans-[Cu(gly)(2)] . 4-BrC₆H₄OH, (I), crystallized in the non-centrosymmetric orthorhombic space group Pca2(1) when trans-bis(glycinato-N,O)copper(II) and 4-bromophenol were allowed to stand in water for several days. Structural analysis reveals that the 4-bromophenol is not coordinated to the copper and that the glycinato units are trans in N,O-bidentate binding mode. The packing of the molecules shows well defined units of (I), interlocked via a network of secondary covalent and non-covalent bonds, with the Cu atom in a [4 + 2] coordination mode.

Mikanolide [systematic names: 1,10:2,3-diepoxy-6,8-dihydroxy-11-vinylgermacr-4-ene 12,14-di- γ -lactone and 7,10a-di-methyl-1a, 1b,2a,6a,7,9a,10,10a-octahydro-4H-6,3-metheno-furo[3,2-c]bisoxireno[f,h]oxacycloundecin-4,8(6H)-dione], C₁₅H₁₄O₆, derived from a variety of Mikania micrantha growing in Portland, Jamaica, contains a methylcyclodecane ring fused to an unsaturated planar α,γ -lactone, an envelope type near-planar vinyl- β,γ -lactone and two epoxide moieties. The crystal packing shows stacks of mikanolide molecules interlocked via a network of non-classical C-H...O hydrogen bonds between the lactone units.

1003. **Bakir, Mohammed A., and Orville Green.** “The Structure of Di-2-Pyridylketone P-Aminobenzoylhydrazone Water Solvate (Dpkabz.H₂O).” *Acta Crystallographica* C58.0263 (2002).**Refereed**

1004. **Bakir, Mohammed A., and C. Gyles.** “Structural Electrochemical and Optical Properties of Dpkfah.” Journal of Molecular Structure 649 (2003): 133 **Refereed**

1005. **Bakir, Mohammed A., Gabriel R. Harewood, Alvin A. Holder, Ishmael Hassan, Tara P. Dasgupta, Paul T. Maragh, and Marvadeen A. Singh-Wilmot.** “5-[(4-Methylphenyl)Diazenyl]Salicylaldehyde.” Acta Crystallographica E61. Section E (2005): 01611-13. **Refereed**

The title compound, $C_{14}H_{12}N_2O_2$, was isolated from the reaction between 4-methylphenyldiazonium nitrite and salicylaldehyde in sodium hydroxide. Structural analysis revealed a nearly planar molecule with the aromatic rings in trans positions about the azo group. The molecule packing shows interdigitated stacks of 12-membered hydrogen-bonded dimers.

1006. **Bakir, Mohammed A., Ishmael Hassan, and Orville Green.** “Manganese Carbonyl Compounds of N, N-Bidentate Di-2-Pyridylketone (Dpk) and N,O,N-Tridentate Hydroxybis (2-Pyridyl) Methanolato (DpkO, OH).” Journal of Molecular Structure 657.1-3 (2003): 75-83.

Refereed

Electrochemical measurements on *fac*-[Mn(CO)₃(dpk)Br] and *fac*-[Mn(CO)₃(dpkO,OH)] revealed solvent dependence and rich redox properties and X-ray studies on *fac*-[Mn(CO)₃(dpkO,OH)] show distorted octahedral geometry around manganese with the major distortion is due to the binding of hydroxybis(2-pyridyl)methanolato (dpkO,OH) anion and anti-parallel tapes of *fac* -[Mn(CO)₃(dpkO,OH)] interlocked via a network of hydrogen bonds. When di-2-pyridyl ketone (dpk) was allowed to react with [Mn(CO)₅Br] in dry diethyl ether under ultrasonic conditions *fac*-[Mn(CO)₃(dpk)Br] was isolated in good yield and when the same reaction was carried out under reflux conditions in toluene *fac*-[Mn(CO)₃(dpkO,OH)] was isolated. Infrared spectra of the isolated compounds confirmed their *fac*-geometry and the presence and absence of the ketonic group of dpk. Electrochemical measurements on *fac*-[Mn(CO)₃(dpk)Br] reveal sensitivity to solvents and the presence of reversible and irreversible electronic transfers. In contrast to *fac*-[Re(CO)₃(dpk)Cl] where noteworthy electrochemical reactions with CO₂ were observed, the electrochemical reactions of CO₂ with *fac*-[Mn(CO)₃(dpk)Br] disclosed no significant reaction. However, when *fac*-[Mn(CO)₃(dpk)Br] was allowed to electrochemically interact with group I and II metal ions considerable electrochemical changes were noted on the second reduction wave that may point to the possible use of *fac*-[Mn(CO)₃(dpk)Br] as an electrochemical sensor for group I and II metal ions. The electrochemical properties of *fac*-[Mn(CO)₃(dpkO,OH)] show the presence of closely spaced irreversible oxidations and probable electrochemical oxidation of coordinated dpkO,OH anion to dpk in dmf. Crystals of *fac*-[Mn(CO)₃(dpkO,OH)] obtained from dimethyl sulfoxide (dmsO) solution of *fac*-[Mn(CO)₃(dpkO,OH)] are in the monoclinic C2/c space group. Structural analysis on *fac*-[Mn(CO)₃(dpkO,OH)] disclosed distorted octahedral coordination about manganese with the major distortion due to the tridentate coordination of dpkO,OH anion and the packing of molecules show stacks of anti-parallel tapes of *fac*-[Mn(CO)₃(dpkO,OH)] interlocked via a network of hydrogen bonds.

1007. **Burke, S. J., Helen M. Jacobs, S. McLean, and Williams F. Reynolds.** “Structural and Spectral Assignment by 2D NMR of a New Prenylated Benzopyrancarboxylic Acid and Structural Reassignment of a Related Compound.” Magnetic Resonance in Chemistry 41 (2003): 145-46. **Refereed**

A new prenylated benzopyrancarboxylic acid, 1a (3,4-dihydro-5-hydroxy-2,7-dimethyl-8-(2-methyl-2butenyl)-2-(4-methyl-1,3-pentadienyl)-2H-1-benzopyran-6-carboxylic acid) was isolated from *Peperomia amplexicaulis* and fully characterized by 1D and 2D NMR and high-resolution mass spectrometry. In the course of this investigation, the structure of a related compound (minus the carboxylic acid group) which was previously assigned as 2b was corrected to structure 1b.

1008. **Calvente, Juan José, German López-Pérez, Pablo Ramírez, Héctor Fernández, María Alicia Zón, Willem H. Mulder, and Rafael Andreu.** “Experimental Study of the Interplay Between Long-Range Electron Transfer and Redox Probe Permeation at Self-Assembled Monolayers: Evidence for Potential-Induced Ion Gating.” Journal of American Chemical Society 127.17 (2005): 6476-86. **Refereed**

Evidence for the competition between long-range electron transfer across self-assembled monolayers (SAMs) and incorporation of the redox probe into the film is reported for the electroreduction of $\text{Ru}(\text{NH}_3)_6^{3+}$ at hydroxyl- and carboxylic-acid-terminated SAMs on a mercury electrode, by using electrochemical techniques that operate at distinct time scales. Two limiting voltammetric behaviors are observed, consistent with a diffusion control of the redox process at mercaptophenol-coated electrodes and a kinetically controlled electron transfer reaction in the presence of neutral $\text{HS}-(\text{CH}_2)_{10}\text{-COOH}$ and $\text{HS}-(\text{CH}_2)_n\text{-CH}_2\text{OH}$ ($n = 3, 5, \text{ and } 10$) SAMs. The monolayer thickness dependence of the standard heterogeneous electron transfer rate constant shows that the electron transfer plane for the reduction of $\text{Ru}(\text{NH}_3)_6$ at hydroxyl-terminated SAMs is located outside the film | solution interface at short times. However, long time scale experiments provide evidence for the occurrence of potential-induced gating of the absorbed structure in some of the monolayers studied, which takes the form of a chronoamperometric spike. Redox probe permeation is shown to be a kinetically slow process, whose activation strongly depends on redox probe concentration, applied potential, and chemical composition of the intervening medium. The obtained results reveal that self-assembled monolayers made of mercaptobutanol and mercaptophenol preserve their electronic barrier properties up to the reductive desorption potential of a fully grown SAM, whereas those of mercaptohexanol, mercaptoundecanol, and mercaptoundecanoic acid undergo an order/disorder transition below a critical potential, which facilitates the approach of the redox probe toward the electrode surface.

Cadina-4,10(15)-dien-3-one (1) was metabolised by *Curvularia lunata* ATCC 12017 in two different growth media to give three metabolites, one of which, 12-hydroxycadina-4,10(15)-dien-3-one (4), was new. Incubation of 3 α -hydroxycadina-4,10(15)-diene (2) with the fungus produced three new analogues, namely, (4S)-1 α ,3 α -dihydroxycadin-10(15)-ene (5), 3 α ,14-dihydroxycadina-4,10(15)diene (6) and 3 α ,12-dihydroxycadina-4,10(15)-diene (7).

1013. **Collins, D. O., Williams F. Reynolds, and Paul B. Reese.** "Aromadendrane Transformations by *Curvularia Lunata* ATCC 12017 ." Phytochemistry 60.5 (2002): 475-81.

Refereed

The naturally occurring sesquiterpene squamulosone (1), isolated from *Hyptis verticillata* (Labiatae), was synthetically reduced to five analogues that were identified as (1S,10S)-9alpha-hydroxy-allo-aromadendrane (2). (1R,10R)-9beta-hydroxyaromadendrane (3), (1S,10S)-allo-aromadendran-9-one (4), (1R,10R)-aromadendran-9-one (5) and aromadendra-1,9-diene (6). Each congener was incubated with the fungus *Curvularia lunata* ATCC 12017 in two different growth media. All the substrates except the deoxy compound 6 underwent a simple redox reaction. Ketone 5 additionally experienced remote hydroxylation while analogue 6, possessing a conjugated diene system, was most extensively metabolised. The substrates and products presented here, but one, are all novel.

1014. —. "New Cembranes From *Cleome Spinosa* ." Journal of Natural Products 67.2 (2004): 179-83. **Refereed**

Examination of the aerial portions of *Cleome spinosa* yielded five new cembranes, named cleospinols A (1), B (3), C (4), and D (5), and the 3'-hydroxy-iso-pentan-10-oate ester of cleospinol A (2). The cleospinols were determined to be derivatives of 10,13-dihydroxy-4,12-dimethyl-1-(1-methylethenyl)-11(E)-cyclotetradecene on the basis of spectroscopic data interpretation.

Refereed

The sesquiterpenes cadina-4,10(15)-dien-3-one (1) and aromadendr-1(10)-en-9-one (squamulosone) (14) along with the triterpenoid methyl ursolate (21) were incubated with the fungus *Mucor plumbeus* ATCC 4740, Substrates 1, 14 and ursolic acid (20) were isolated from the plant *Hyptis verticillata* in large quantities. *M. plumbeus* hydroxylated 1 at C-12 and C-14. When the iron content of the medium was reduced, however, hydroxylation at these positions was also accompanied by epoxidation of the exocyclic double bond. In total nine new oxygenated cadinanes have been obtained. Sesquiterpene 14 was converted to the novel 2alpha,13-dihydroxy derivative along with four other metabolites. Methyl ursolate (21) was transformed to a new compound, methyl 3beta,7beta,21beta-trihydroxyursa-9(11),12-dien-28-oate (22). Two other triterpenoids, 3beta,28-dihydroxyurs-12-ene (uvaol) (23) and 3beta,28-bis(dimethylcarbamoy)urs-12-ene (24) were not transformed by the micro-organism, however.

Polarized-ion models-with and without dipole reaction fields and charge-quadrupole interaction-are evaluated in calculating atomization energies, bond angles, and bending force constants of groups of 2 and 12 dihalides. A study of the sensitivity to changes in the input parameters reveals a strong dependence on dipole polarizabilities. The charge-quadrupole bending terms of a multipole expansion are important for quasi-linear molecules, where the preceding terms in the expansion tend to cancel each other. They normally stabilize the linear geometry, but enhance bent structures, if a certain criterion for the ratio of quadrupole polarizabilities of metal and halide ions is fulfilled. The models explain the bent alkaline earth halides, but fail spectacularly for the group 12 halides-HgBr. The charge - quadrupole terms of a multipole expansion are important for quasi-linear molecules, where the preceding terms in the expansion tend to cancel each other. They normally stabilize the linear geometry, but enhance bent structures, if a certain criterion is fulfilled. The models explain the bent alkaline earth halides, but fail spectacularly for the group 12 halides - HgBr₂ and HgI₂ are even calculated as unstable relative to the constituent atoms. The unexpected weakness of ionic bonds is related to the large increase of the ionization energies by relativistic effects and the lanthanide contraction.

1023. ——. "Valence-State Atoms in Molecules.7.Influence of Polarization and Bond-Charge on Spectroscopic Constants of Diatomic Molecules." *Journal of Physical Chemistry A* 108.4 (2004): 595-606.

The polarizable valence-state-atoms-in-molecules (pVSAM) model describes the electron-pair bond in A-B molecules by superposing core-polarized A^+B^- , A^-B^+ , and A:B structures, whose weights are determined by electronegativity equalization. The polarizable valence state potential energy curve (pVS-PEC) is derived through the systematic improvement of the valence state potential energy curve (VS-PEC) [Gardner, D.O.N.; von Szentpály, L.J. Phys. Chem. A 1999, 103, 9313] and is given as $U(R) = -[(K_1/R) + (K_2/R^4) + (K_3/R^7)] + (T/R) \exp(-\lambda R)$. The first bracketed term contains the Coulomb, charge-induced dipole, and induced dipole-induced dipole terms, derived from weighted ionic and covalent bond-charge contributions. The potential is tested on a broad variety of homonuclear diatoms and heteronuclear halides and hydrided (a total of 52 molecules). The accuracies of the dimensionless vibration - rotation coupling constant (F) and the anharmonicity constant (G) for the halides of the alkali and coinage metals are significantly better than those of the Morse, Rydberg, simple bond-charge, and Rittner

potentials. Adding core polarization to the VS-PEC reduces the average unsigned errors in the spectroscopic constants of 47 diatomic molecules from 17.1% to 7.5% in F and 18.9% to 7.8% in G, whereas those of the Morse potential amount to 32.6% and 31.4%, respectively.

An efficient route to the synthesis of benzothiazoles from ortho- methoxythiobenzamides via the ipso substitution of an aromatic group is presented, and the mechanism of the Jacobson synthesis of benzothiazoles is further investigated

1025. **Ellis, Henry A., Nicole A. White, Ishmael Hassan, and R. Ahmad.** “A Room Temperature Structure for Anhydrous Lead (II) Decanoate.” *Journal of Molecular Structure* 642 (2002): 71-76. **Refereed**

The room temperature structure of anhydrous lead (II) decanoate has been studied using X-ray diffraction, infrared spectroscopy and polarizing light microscopy. A triclinic unit cell with dimensions: $a = 8.529$ (3), $b = 11.207$ (4), $c = 28.451$ (2) Å, $\alpha = 83.814$ (2), $\beta = 88.971$ (2), $\gamma = 65.143$ (3); $Z = 4$, $M = 549.2$ g mol⁻¹, $D_c = 1.50$ (6), $D_m = 1.68$ (2) is indicated. Infrared and powder diffraction data point to a structure containing both bidentate bonding and carboxylate bridging around, possibly eight coordinated lead. A bilayer arrangement of chains at an average 68° to planes containing Pb²⁺ ions is proposed. Each molecule is situated at the corners and center of the unit cell with possibly P1 symmetry as is the case for copper (II) decanoate.

1026. **Ellis, Henry A., Nicole A. White, Richard A. Taylor, and Paul T. Maragh.** “Infrared, X-Ray and Microscopic Studies on the Room Temperature Structure of Anhydrous Lead (II) N-Alkanoates.” *Journal of Molecular Structure* 738 (2005): 205-10. **Refereed**

The room temperature structure of a series of even-chain length lead (II) n-alkanoates have been studied using infrared spectroscopy, X-ray diffraction and polarizing light microscopy. Whilst the bonding is the same for both long and short chain compounds, where four carboxylate groups form an unsymmetrical bidentate bond with a lead atom, with possible carboxylate bridging to adjacent lead atoms, at least for the short chain length compounds, the arrangement of hydrocarbon chains within a lamella is different. Both X-ray and microscopic studies show that for short chain compounds, hydrocarbon chains are arranged as bilayers within a lamella and tilted with respect to the lead basal plane. For the long chain compounds, it is proposed that the chains are arranged as a monolayer within a lamella, in an alternating arrangement, and slightly tilted with respect to the lead basal plane. For all the compounds, X-ray data point to a triclinic unit cell containing four molecules per unit cell with P1 symmetry, and chains oriented along the c axis.

While use of asbestos materials in developed nations has been decreasing because of the harmful health effects of asbestos dust mining, processing and use of the ancient material in developing countries is increasing. The regulatory mechanism for use, handling and disposal of asbestos and associated waste in developing countries are weak and information on asbestos-related diseases is scanty but emerging. We identify lack of epidemiological data on asbestos health effects as a major gap to be bridged in the promotion of occupational and environmental health in developing countries. Without data on local situations, diseases such as asbestosis and mesothelioma remain too obscure to assist the campaign for appropriate regulation of asbestos usage or attracting attention to abominable industrial practices generally.

Williams.** "Phthalimides: Supramolecular Interactions in Crystals, Hypersensitive Solution H-1-NMR Dynamics and Energy Transfer to Europium(III) and Terbium(III) States." Molecules 8.7 (2003): 565-92. **Refereed**

Detailed crystal structures and H-1-NMR characteristics of some alkylaminephthalimides, including dendritic polyphthalimides, are reported. These investigations were undertaken in order to obtain a better understanding of the relationship between solid-state supramolecular interactions, their persistence in solution and associated dynamics of magnetically hypersensitive phthalimide aromatic AA'BB'-AA'XX' proton NMR resonances. Some alkylamine phthalimides feature folded molecular geometries, which we attribute to n-pi interactions among proximal amine-phthalimide sites; those alkylamine-phthalimides that have no possibility for such interactions feature fully extended phthalimide functionalities. Accordingly, alkylamine phthalimide compounds with folded solid-state geometries feature solvent and temperature dependent hypersensitive AA'BB'-AA'XX' H-1-NMR line profiles, which we attribute to the n-pi interactions. Luminescence of Eu³⁺(D-5(o)) and Tb³⁺(D-5(4)) states show well defined metal ion environments in their complexes with dendritic phthalimides, as well as relatively weak phthalimide-lanthanide(III) interactions.

Proceedings of the Sixth Conference, Faculty of Pure and Applied Sciences: Kingston, Jamaica: Faculty of Pure and Applied Sciences, University of the West Indies, 2003.

The title dimer complex in aqueous solution undergoes a rapid one electron transfer reaction with hexacyanoferrate (II) ions followed by a much slower process which involves the decomposition of the dimer complex to form a

monomeric iron (II) species. The monomeric iron (II) species then undergoes a slow complex reaction to produce a blue complex, very similar in nature to Prussian blue. It is proposed that the mechanism of the first electron transfer process is outer sphere and the subsequent process involves both adduct formation followed by electron transfer. The rate of the electron transfer depends on the concentration of alkali metal cations in solution, revealing the possibility of the formation of an ion-triplet before electron transfer. An overall mechanistic scheme for these stages will be discussed in terms of the kinetic results obtained.

The rare earths are a group of elements ranging from cerium to lutetium (inclusive of lanthanum, yttrium and scandium), whose peculiar magnetic, spectroscopic and chemical properties have resulted in wide and extensive studies of their compounds. Their current and potential applications have stimulated great interest and include their

use as luminescent probes, contrast agents for magnetic resonance imaging (MRI), diagnostic/therapeutic radioisotopes, as well as catalysts for the hydrolysis of DNA and RNA. Our studies have been inspired by these applications and have thus far produced novel polynucleating macrocyclic and acyclic Schiff's base chelates with unusual recognitive sites. These were synthesized by templated condensation reactions in the presence of rare earth salts, and were definitively characterized by single crystal X-ray diffraction. Structural, luminescence spectroscopic and decay dynamical results will be presented.

The theoretical basis for the calculation of acid dissociation constants in the lowest excited singlet or triplet state of organic compounds has been reexamined in light of a recent study on solvatochromism. A mathematical analysis based on the Onsager cavity model reveals that the absorption or emission frequency of an acid and its conjugate base, as they appear in the Förster equation, should be replaced with the averages of absorption and emission frequencies corresponding to the 0-0 transition of acid and base, respectively, in order to account for Franck-Condon effects on the free energy balance. The free energy of spontaneous medium relaxation is found to be the same for absorption and emission, and proportional to one-half of the Stokes shift.

The main premise of the proposed method, besides the obvious requirement that both the acid and its conjugate base should fluoresce or phosphoresce, is that each excited state exists long enough for equilibrium with the medium to be established prior to emission.

An analysis of equilibrium size distributions of circular liquid-condensed (LC) domains in amphiphilic monolayers at the air/water interface, gleaned from microscopic images, is presented in terms of Gaussians fitted to a theoretical expression derived previously. It is demonstrated how, in principle, important properties of the monolayer, such as molecular dipole moments of surfactant head groups and line tension of the liquid-condensed/liquid-expanded phase boundary, can be obtained by combining the results of this simplified analysis with information from X-ray diffraction or surface pressure measurements.

Ronald Fawcett.** "Calculation of Ionic Surface Excess Concentrations in the Diffuse Double Layer at Low Field Strengths for a Restricted Primitive Model Electrolyte." Journal of Electroanalytical Chemistry 575.2 (2005): 211-19. **Refereed**

Analytical expressions have been derived for the ionic surface excesses of a restricted primitive-model z-z electrolyte near a charged wall, by combination of a thermodynamic result with a recently derived equation for the surface potential as a function of salt concentration and surface charge density within the context of the Fawcett-Henderson method. This approximate result accounts for the finite size of ions and applies in the limit of low field strengths at the surface, corresponding to absolute surface charge densities not exceeding ca. $10 \mu\text{C cm}^{-2}$ and concentrations of at least 0.1 M. The theoretical expression has been tested via comparison with predictions based

on Gouy-Chapman theory and data obtained with Monte Carlo simulations, and has been found to show a superior performance at high concentrations and large ion sizes in the case of 1-1 electrolytes and, to a lesser extent, 2-2 electrolytes.

<http://search.epnet.com/login.aspx?direct=true&db=cmedm&an=15773117>. **Refereed**

The interface between an electrolyte solution and a metal electrode coated with an oxidatively adsorbed, redox-active monolayer of long-chain thiols has been examined from a thermodynamic point of view. The electrode potential is assumed to vary within the region where no reductive desorption of the thiol occurs, so that the interface may formally be regarded as ideally polarizable. The analysis leads to an expression describing the potential dependence of interfacial tension in terms of the charge density on the metal, salt concentration, dielectric properties of the organic film, and the redox properties of the active terminal groups, which vary with the (average) distance from the electrode surface. This result generalizes the classical Lippmann equation to modified electrodes of the type considered.

1060. **Ramdon, Dwight C., Donovan A. Dixon, and Tara P. Dasgupta.** “Mechanism of Reduction of Chromium (VI) Ion by 2-Mercaptosuccinic Acid in Aqueous Solution.” Inorganica Chimica Acta 331 (2002): 178-87. **Refereed**

The kinetics of the reduction of the chromium (VI) ion by 2-mercaptosuccine acid (thiomalic acid) were studied by rapid scanning stopped flow spectrophotometry. The conditions used were $[\text{Cr(VI)}]_{\text{T}} = 0.20 \text{ mM}$, $[\text{MSA}]_{\text{T}} = 5-90 \text{ mM}$, $3.0 \leq \text{pH} \leq 5.6$ in citric acid-phosphate buffer, or $3.3 \leq \text{pH} \leq 5.4$ in 0.40 M acetic acid-acetate buffer, $20.0 \leq T \leq 35.0 \text{ }^{\circ}\text{C}$ at $I = 0.50 \text{ M}$ (NaClO_4). Spectrophotometric titration at 350 nm indicates the stoichiometry of the reaction to be 1:3. The kinetics of both formation and decay of the intermediate chromium (VI) thioester were followed at $\lambda_{\text{max}} = 425 \text{ nm}$ and rate expressions, specific rate constants and corresponding activation parameters were derived from the proposed mechanism. The acetic acid-acetate buffer was found to catalyze the formation but not the decay rate of the intermediate. The citric acid-phosphate buffer and dissolved oxygen did not have any significant effect on the reaction rates. The justification of the mechanism was discussed in terms of standard biological conditions.

1061. —. “Mechanistic Studies of the Reaction Between Thioglycolic Acid and Chromium (VI): Substitution, Isomerisation, and Electron Transfer.” Inorganic Reaction Mechanisms 5 (2004): 1-15. **Refereed**

Thioglycolic acid, H_2TGA , containing a reactive sulphhydryl group, has been shown to reduce Cr(VI). The experimental conditions were $[Cr(VI)]_T = 0.20$ mM, $[TGA]_T = 22 - 100$ mM, $15.0 \leq T \leq 30.0$ °C, $2.66 \leq pH \leq 4.66$ (TGA self -buffer) or $2.74 \leq pH \leq 6.05$ (citric acid-phosphate) at a constant ionic strength of 0.50 M ($NaClO_4$). The reaction was studied using rapid scanning stopped-flow spectrophotometry at $\lambda = 425$ nm. The kinetics of the reaction showed distinct spectral evidence for the formation of an intermediate that was subsequently followed by a slower, bimolecular redox process leading to the formation of the final products. Based on the analysis of the experimentation data, the formation of the intermediate involved the conversion of an O-bonded Cr(VI)-thioglycolate intermediate, $-O_3CrOC(O)CH_2SH$, to the S-bonded type $-O_3CrSCH_2COOH$, prior to the redox step.

Normal acid-base equilibria of thioglycolate ($H_2TGA / HTGA^-$) and chromate species ($HCrO_4^- / CrO_4^{2-}$) were found to be inadequate to explain the overall mechanism. Instead, the facile reactions of both O-bonded and S-bonded Cr(VI)-thioglycolate intermediates were seen to be influenced by their own proton dependency. It was found that depending on the nature of the buffer used, some catalytic effects were evident, but the complete pH profile obtained was inherently peculiar to the reaction involving the main reactants. Added metal ions such as Cu^{2+} and Zn^{2+} are implicated in the overall course of the reaction, and their effects also seem to be determined by the concentration of $[H^+]$ utilized.

Extensive investigation of the catalytic degradation of polychlorinated biphenyls (PCBs) was carried out in solution using some peroxo complexes of chromium (IV) and iron complexes in conjunction with hydrogen peroxide. The change in concentration of PCBs was measured by using a gas chromatograph attached to an electron capture detector. A mass spectrometric detector was used. The results obtained are discussed.

1065. —. “The Determination of the Levels of Polychlorinated Biphenyls (PCBs) in Some Urban and Rural Areas of Jamaica.” Jamaican Journal of Science and Technology 15 (2004): 2-10. **Refereed**

Studies were done to ascertain the levels of PCBs in soil, water and sediments in some urban and rural areas in Jamaica. All the soil samples collected contained less than 10 ppm PCB and PCB was found only in soil samples which were collected from sites where transformers were stored or are in use. The mean concentrations of PCBs in the urban and rural soil samples were 0.7 and 0.2 mg/kg respectively with over 80% of the samples containing less

than 2.0 mg/kg. The median concentration for the urban soil sample was 1.4 mg/kg while that for the rural was less than 0.1 mg/kg. The concentration of PCBs was measured either by using a gas chromatograph attached to an electron capture detector or a mass spectrophotometric detector.

A series of novel hexanuclear lanthanide (III)-hydroxo complexes were prepared by reacting hydrous lanthanide salts with 1-aziridineethanol. Elemental analysis, IR and luminescence were used to characterize the complexes. Room temperature emission and excitation spectra for the europium (III) complex show typical $\text{Eu}^{3+}({}^5\text{D}_0 \rightarrow {}^7\text{F}_j)$ transitions. The $\text{Eu}^{3+}({}^5\text{D}_0 \rightarrow {}^7\text{F}_0)$ emission region is split into two as expected for crystals with two different Eu^{3+} environments. The synthesis, structures and luminescence spectroscopy and decay behaviour of the hexanuclear complexes will be presented.

“Bis(Mu-2,6-Diformyl-4-Methylphenolato)Bis[Bis(2,6-Diformyl-4-Methylphenolato)Neodymium(III)].” Acta Crystallographica Section E-Structure Reports Online 61.Part 6 (2005): M1009-M1011 .**Refereed**

The title compound, [Nd-2(C₉H₇O₃)(6)], crystallizes from an anhydrous alcoholic mixture of neodymium perchlorate, 2,6-diformyl-4-methylphenol and sodium hydroxide. The structure consists of discrete dinuclear molecules with Nd-III ions in eightfold coordination environments. The complete molecule is generated from the asymmetric unit by a crystallographic center of symmetry. Intramolecular and intermolecular pi-pi stacking and C-(HO)-O-... interactions help to stabilize the crystal packing.

1075. Smith, James N., and Tara P. Dasgupta. “Mechanism of Nitric Oxide Release.I. Two-Electron Reduction of Sodium Nitroprusside by L-Cysteine in Aqueous Solution.” Inorganic Reaction Mechanisms 3 (2002): 181-95.**Refereed**

Sodium nitroprusside (SNP) is a well-known vasodilator, which activates the cytosolic isozyme guanylate cyclase. It is quite stable by itself in aqueous solution and in the dark, but produces nitric oxide spontaneously under the appropriate reducing conditions. Both the neutral nitric oxide (NO) and the nitroxyl anion (NO⁻) can be produced from SNP depending on the condition employed. NO release is favored at lower pH and cysteine concentration while NO⁻ formation is more likely to occur at higher pH (<7) and cysteine concentration. NO was measured by electrochemical method and the chemical detection of NH₂OH and NO₂ are evidences of NO⁻ formation. The mechanism of the reaction was found to be very complicated and involved three clear stages. NO and NO⁻ are postulated to form in the first and third stages, respectively. All three stages showed cysteine dependence and were also affected by the pH of the solution. The first two stages resembled stepwise reversible two-electron reduction of NO⁺ to NO⁻ and are similar in rates. However the third stage is the slowest irreversible and rate-determining substitution of NO⁻ by cysteine in the reduced nitroprusside ion. Increased absorption occurs between 250 and 500 nm for the first two stages with absorption maxima at about 340 nm for the first two stages which signals NO reduction in nitroprusside. A decrease in absorption in the same region, which signals loss of NO⁻ was observed in the same region, which signals loss of NO⁻ was observed for the third stage of the reaction sequence. Cyanide release occurs in the first stage and the addition of NaCN significantly retards the reaction rate proving the reversible loss of CN⁻ from the nitroprusside ion. Transition metal ions are known to catalyze the decay of nitrosocompounds and addition of Cu²⁺ to reaction solutions showed significant catalysis and was especially pronounced in the final stage.

Factors that influence aggregation of lanthanide(III) (Ln(III)) ions to form polynuclear complexes were studied utilizing 1-aziridineethanol as a versatile source of macrocyclic and acyclic chelates. The facile ring-opening cyclo-oligomerization of 1-aziridineethanol leads to the formation of a series of polyaza cyclic oligomers (series A). In the presence of ethylenediamine, a competing N-alkylation reaction occurs to produce a new class of acyclic ligands (series B). The cyclo-oligomerization-of four 1-aziridineethanol units is the most favorable process, leading to the formation of the 12-membered cyclen-type macrocycle, H4L1 (1,4,7,10-tetrakis(2-hydroxyethyl)-1,4,7,10-tetraazacyclododecane). Ring-opening cyclo-oligomerization of 1-aziridineethanol in the presence of Ln(III) ions produces self-assembled mononuclear, tetranuclear, and pentanuclear compounds of H4L1. In the presence of ethylenediamine, oligomerization of 1-aziridineethanol results in a dinuclear complex of an acyclic poly(amino-alkoxide) H2L2. The coordinative unsaturation of (i) the alkoxy sites of $[H_xL1]_{(x-4)}$ (where $x < 4$) and (ii) Ln(III) ions in coordination numbers less than nine are critical factors in the formation of the polynuclear Ln(III) complexes. The identities of mononuclear, dinuclear, tetranuclear, and pentanuclear complexes herein discussed were established by X-ray crystallography.

1089. **Arimah, Benedict C.** “Measuring and Explaining the Provision of Infrastructure in African Cities.” International Planning Studies 8.3 (2003): 225-40.

There are few studies that investigate the provision of infrastructure in Africa from a cross-city perspective. This can be attributed to the dearth of reliable data. The United Nations Human Settlements programme (UN-Habitat) through its Global Urban Indicators Programme recently completed the collection of an extensive set of urban indicators for 237 cities worldwide. Drawing on the African component of this database, this paper measures and accounts for intercity variations in the provision of infrastructure. The empirical analysis reveals that the provision of infrastructure in African cities can be measured in terms of a single dimension of basic infrastructure, which comprises water, electricity, sewerage, sanitation and telecommunication services. Further analysis shows that the most important variables explaining intercity differences in the dimension of basic infrastructure are: income as measured by GDP per capita; external debt burden of the country in which the city is located; city size; public sector expenditure on infrastructure; local government’s capital expenditure; and the proportion of the local authority’s revenue derived from user charges.

1090. —. “Poverty Reduction and Human Development in Africa.” Journal of Human Development 5.3 (2004): 399-415. **Refereed**

This paper uses cross-national data to investigate the extent to which the adoption of human development strategies has resulted in a reduction of poverty in Africa. Inter-country variations in income and human poverty reinforce the established patterns of well-being within the continent, as countries in Northern and Southern Africa have the lowest levels of poverty. The empirical analysis reveals that inter-country differences in poverty levels can be accounted for by variables indicative of the different facets of human development. These include public expenditure on education, primary school enrolment, female educational enrolment, expenditure on health, and good governance. Other significant variables apart from those pertaining to human development are economic growth, high external debt, the prevalence of HIV/AIDS and the geographical disadvantage of being a landlocked country. The paper also shows that foreign aid has had a limited effect on poverty reduction in Africa.

1091. —. “What Drives Infrastructure Spending in Cities of Developing Countries?” Urban Studies 42.8 (2005): 1345-68.

There exists a dearth of empirical studies on what determines infrastructure spending in cities of developing countries. This in part can be attributed to the absence of quality data and the tendency for researchers to gloss over variations in infrastructure expenditure in or across developing world cities in the general belief that investment in infrastructure is generally low. Using the United Nations Human Settlements Programme’s global urban indicators database, this paper examines variations in infrastructure spending across cities in developing countries with a view to identifying the factors that explain these differences. The empirical analysis identifies substantial intercity variations in infrastructure spending both across and within the regions of Africa, Asia, the Middle East, Latin America and the Caribbean, and the economies in transition. Further analysis suggests that intercity variations in infrastructure spending are accounted for by differences in the macroeconomic environment, urban growth rate, quality of governance and financial capacity of municipal governments.

1092. **Bailey, Corin.** “Education and Social Exclusion.” Proceedings of the Sixth Conference, Faculty of Pure and Applied Sciences: Kingston, Jamaica: Faculty of Pure and Applied Sciences, University of the West Indies, 2003. 32.

This paper is part of a wider study which examines crime in the Kingston Metropolitan Area (KMA), Jamaica, as a reaction to social exclusion. The term social exclusion refers to a condition in which a large segment of the society is shut out from the systems which determine their level of social integration in the society. One of these systems is education and this is the focus of this paper. The methodology adopted is triangulation, a mixed methodology that, metaphorically, has the strengths of the geometric triangle. Interviews in four social areas in the KMA established the educational achievements of a random sample of household heads. Focus group sessions with two age cohorts in two areas probed the achievements, aspirations, and perceived barriers to the realising of the goals of participants. The test scores, sending schools and home addresses of students selected by a traditional and a new high school in 2001, as well as the qualifications of teachers were examined.

Certain ‘choices’ define the educational careers of students and there is inequality of educational opportunity. The

few students in poor areas who manage to beat the odds are creamed off by top schools creating a situation in which students in secondary schools in poor areas perform in accordance with how the society sees them.

1093. **Bailey, Wilma R., Clement Branche, and Aldrie Henry-Lee.** "Gender Relations and Conflict Management in Inner-City Communities in Jamaica: The Importance of Community Participation." Participatory Planning in the Caribbean: Lessons From Practice. Editors Jonathan Pugh and Robert B. Potter. England: Ashgate, 2003. 139-54.

(Also published by Ashgate in Burlington, Vermont, USA.)

Describes an attempt to promote peaceful means of resolving conflict in three low - income communities in the Kingston Metropolitan Area in Jamaica: those of Maverly, Drewsland and Southside. It arose out of the fact that in the context of a difficult urban economic and institutional decay, violence had become a part of the accepted logic. Community workers or 'change agents' were given basic conflict resolution skills and were trained to work with individuals who felt that they could benefit from the intervention. The change agents worked in communities where disputes were of an interpersonal nature involving people who have close relationships; where the activities of criminal gangs and political factions frequently erupted into street violence. Moreover, because of entrenched social identities, conflicts spilled over community boundaries to engulf the wider urban society. In this situation, the conflict resolution strategy adopted proved to be too individualistic and interpersonal. What was needed was a programme of community mediation in which the impartial change agents were given the tools to intervene in conflicts, allowing participants to air their grievances, and assist in the negotiation of agreement. (5 appendixes (on CD), and 5 plates)

This report identifies and characterizes candidate ground-water flow zones in the upper part of the shallow, eogenetic karst limestone of the Biscayne aquifer in the Lake Belt area of north-central Miami-Dade County using cyclostratigraphy, ground-penetrating radar (GPR), borehole geophysical logs, and continuously drilled cores. About 60 miles of GPR profiles were used to calculate depths to shallow geologic contacts and hydrogeologic units, image karst features, and produce qualitative views of the porosity distribution. Descriptions of the lithology, rock fabrics, and cyclostratigraphy, and interpretation of depositional environments of 50 test coreholes were linked to the geophysical interpretations to provide an accurate hydrogeologic framework. Molluscan and benthic foraminiferal paleontologic constraints guided interpretation of depositional environments represented by rock fabric facies. Digital borehole images were used to characterize and quantify large-scale vuggy porosity. Preliminary heat-pulse flowmeter data were coupled with the digital borehole image data to identify candidate ground-water flow zones.

1100. **Cunningham, Kevin J., Michael A. Wacker, Edward Robinson, Cynthia J. Gefvert, and Steven L. Krupa.** Hydrogeology and Ground-Water Flow at Levee 31N Miami-Dade County, Florida, July 2003, to May 2004. U.S. Geological Survey Scientific Investigations Map I-2846: U.S. Department of the Interior, U.S. Geological Survey, 2004. <http://sofia.usgs.gov/publications/sim/I-2846/>.

The stratigraphy of the Biscayne aquifer at the Levee 31N study area is characterized by vertical lithofacies successions (VLSs) that occur individually or bundled within high-frequency cycles (HFCs). The VLSs are the smallest set of genetically related lithofacies and represent the fundamental building blocks of the Biscayne aquifer. The HFCs are defined on the occurrence of regional-scale bounding upper and lower exposure surfaces and their likely relation to fifth-order, 10- to 100-kiloyear cyclic sea-level events. The VLSs are related to a single rise and fall in relative sea level in the less than 10- to 100-kiloyear duration range (fifth order or higher), suggesting an association with sub-Milankovitch frequencies observed in patterns of cyclic deposition within the Fort Thompson Formation.

 The feelings of young people towards their surroundings have often been neglected in studies of Third World cities. In this paper, I examine these views in Kingston, Jamaica: a large, poor city with high socio-economic inequality. The young people surveyed have generally positive feelings towards their surroundings, yet are frequently excluded from making decisions about the ways in which these are managed. Their responses shed light on some of the main problems facing the city, and provide a strong case for young people’s inclusion in local sustainable development planning.

 The authors are uniquely positioned to examine the vicissitudes of publishing these various volumes, having edited the abstracts and field guides (Donovan 1998) and *Transactions* (Jackson 2002) of the 15th Caribbean Geological Conferences (CGC), held in Jamaica in 1998. Our experiences have strongly indicated to us that a reassessment of the role of these various publications is desirable, perhaps essential, for their continued health and vitality. We question whether what has been the accepted pattern in the past is desirable for the 21st Century. The purpose of the present contribution is to document those factors that we consider need examination when publishing this trinity of CGC publications, put forward our arguments for future requirements and report the conclusions of an energetic discussion on the topic at the 16th CGC in Barbados in June 2002. The underlying question that prompted us to write

this essay can perhaps be summarized as “Should we continue to publish the *Transactions* and, if so, why and how (and for whom)?” This essay, both produced for and arising from the 16th CGC, will, we hope, help to encourage a more active and positive participation by delegates in all aspects of the publication process at future meetings. We hope our arguments, ideas and conclusions are of broad interest to a range of scientific disciplines.

The orbitoidal larger foraminifer *omphalocyclus maldonensis* n. sp. is described from the Maldon inlier of northwestern Jamaica, being the first record of this genus from the island. The limestone in which it occurs contains the upper cretaceous (upper maastrichtian) *Titanosarcolithes* rudist fauna, together with larger foraminiferal specimens identified as *Orbitoides megaliformis* Papp & Küpper. The new species differs from *Omphalocyclus macroporus*, the only other widely recognized species, in possession a much smaller nucleus. At least some of the earlier records of *Omphalocyclus* from the upper cretaceous of Venezuela and Cuba should probably be referred to *O. maldonensis*. *J. Micropalaeontol.*

1120. **Miller, David J., and Simon F. Mitchell.** “Palaeokarstic Surfaces in the Upper Cretaceous Limestones of Central Jamaica.” Cretaceous Research 24 (2003): 119-28. **Refereed**

Two prominent pitted surfaces in rhythmic, late maastrichtian, rudist-bearing limestones in central Jamaica are described. The lower surface is pock-marked with small pits that form a nodular, mamillated surface. The pits are roughly circular to gently elliptical in plan view. They vary in diameter from 5-170 mm and in depth from 5-90 mm, and are oriented perpendicular to bedding. This surface is buried beneath a lignite-rich siltstone bed. The upper surface contains microkarren phenomena represented by small cylindrical potholes up to 40 mm in diameter and 30 mm deep. These surfaces are interpreted as palaeokarstic because the pits are: (1) perpendicular to bedding and not the present land surface; (2) infilled with very poorly sorted siltstone, and (3) overlain by lignitic shales indicating terrestrial influx. The presence of two palaeokarstic surfaces in late maastrichtian limestones suggest short-period cycles in relative sea level, consistent with glacial-eustatic driving mechanisms.

1121. **Mitchell, Simon F.** “Morphology, Microstructure and Stratigraphy of Some Late Cretaceous Radiolitid Rudists From Jamaica.” Geologia Croatica 56.2 (2003): 149-71. **Refereed**

Radiolitid rudists from the upper maastrichtian of Jamaica include genera *Bournonia*, *Biradiolites* and *Thyrastylon*. Three species of *Bournonia* were recognised, *B. cancellata* WHITFIELD, *B. barretti* TRECHMANN and *B. thiadensi* VERMUNT. *B. cancellata* evolves into *B. barretti* by the acquisition of costae on the anterior side. The species of *Bournonia* are characterised by a distinctive cardinal apparatus, a thick inner shell layer, and an outer shell layer composed of cellular microstructure. Two species of *Biradiolites* are recognised - *B. rudissimus* TRECHMANN has an outer layer composed of cellular microstructure with occasional bands of compact microstructure, particularly in the radial bands, and *B. jamaicensis* TRECHMANN has a very well organised outer layer with an inner band of cellular microstructure and an outer band of compact microstructure. *Biradiolites* and *Thyrastylon* have a similar dentition, a thin inner layer and similar wall structures in the outer layer. *Thyrastylon* is distinguished from *Biradiolites* by the infolding of the radial bands in RV and by the presence of oscules in LV. The evolutionary change from *Bo. cancellata* to *Bo. barretti*, and the first appearance of *Bi. jamaicensis* are probably useful biostratigraphic markers of the upper maastrichtian.

1122. —. “Palaeoecology of Corals and Rudists in Mixed Volcaniclastic-Carbonate Small-Scale Rhythms (Upper Cretaceous, Jamaica).” Palaeogeography, Palaeoclimatology, Palaeoecology 186 (2002): 237-59. **Refereed**

The Guinea Corn formation (central Jamaica, West Indies) is represented by alternating platform carbonates and volcaniclastic sandstones and siltstones and represents the most landward shift of facies in an Upper Campanian to maastrichtian transgressive-regressive cycle. The succession consists of 2-30-m-thick rhythms comprising a lower volcaniclastic siltstone/sandstone division; a middle volcaniclastic siltstone/limestone with abundant corals or the rudist *Antilocaprina stellata*; and an upper division of rudist rudstones and floatstones. The lower division consists of either bioturbated sandy siltstones with lignite and abundant gastropods and infaunal bivalves (lower rhythms in

the Guinea Corn Formation), or interbedded volcanoclastic siltstones and normally graded sandstones. The rudist limestones are parallel-bedded and consist of high-abundance mono- to paucispecific assemblages. The boundary between the middle and upper parts of rhythms contains a concentration of oncoids with coral nuclei and a mantle of microbial laminates, red algae and serpulids. Four coral assemblages are recognised based on diversity and coral morphology. The *Paracycloseris-Dasmosmilia* assemblage occurs in the lower division of the rhythms and is interpreted as a soft-substrate assemblage that was adapted to elevated nutrient levels. The *Ovalastrea-Actinacis*, *Actinacis-Multicolumnastrea* and *Actinacis-Calamophyllia-Gyrodendron* assemblages occur in the middle parts of the rhythms and consist of bedded rudstones, rudstone mounds and rarer platestones, pillarstones and mixstones. Polyparia arrangements, colony morphology and low diversity suggest the *Ovalastrea-Actinacis* and *Actinacis-Multicolumnastrea* assemblages were adapted to high sedimentation rates. The more diverse *Actinacis-Calamophyllia-Gyrodendron* assemblage is interpreted to have grown under more optimum conditions (low sedimentation rates and high light intensities). Rudists are classified on their growth orientation (elevator, clinger, recumbent) and on their communal relationships (isolated or clustered). The cluster elevator *Biradiolites mooretownensis* occurs in the lower division of rhythms and the recumbent *A. stellata* occurs in the middle part of rhythms. The upper part of rhythms contains abundant rudists including isolated elevators (*Antillocaprina occidentalis*), cluster elevators (*Bournonia* spp., *Biradiolites jamaicensis*, *Thyrastylon* spp. and *Chiapasella radiolitiformis*) and clingers (*Plagioptychus* spp.), with the topmost part contains the large recumbent *Titanosarcolithes*.

1123. —. “Sedimentology and Stratigraphy.” Science, Technology & Innovation: UWI Mona Leading the Nation. Mona, Jamaica: University of the West Indies, 2004. 93-96.

Reports on the completed study of sedimentology and stratigraphy that the author has undertaken over the last years. The analysis of the findings of these cumulative research/projects and their application to the development of resources in Jamaica is considered.

1124. —. Sedimentology and Tectonic Evolution of the Cretaceous Rocks of Central Jamaica: Relationships to the Plate Tectonic Evolution of the Caribbean.

Detailed mapping and logging of successions in the Central inlier of central Jamaica has been undertaken. The succession contains three angular unconformities that allow the division of the succession into four units. The oldest rocks, the Arthurs Seat Formation, consist of a lower series of tholeiitic basaltic lavas and an upper unit of poorly sorted conglomerates with some calc-alkaline lavas. They represent lavas and proximal volcanoclastic deposits of a late early or early late cretaceous volcanic center. The late santonian to early Campanian Crofts Hill Synthem (Peters Hill Formation, Back River Formation [new], and Dawburns Content Formation [new]) rests unconformably on the Arthurs Seat Formation. It represents a deepening-upward succession, beginning with rudist limestones and ending in turbiditic sandstones and shales. The unconformity at the base of the Crofts Hill Synthem is interpreted as the result of a rifting event that created an intra-arc to back-arc basin, in which the rocks of the Crofts Hill Synthem were deposited. The Crofts Hill Synthem is cut by late Campanian thrust faults that dip toward the north. This thrusting was caused by the collision of the western part of the Greater Antilles arc with the Yucatán Peninsula. The Maastrichtian Kellits Synthem represents a transgressive-regressive cycle that rests unconformably on the rocks of the Arthurs Seat Formation and Crofts Hill Synthem. The succession begins with braided stream deposits (Slippery Rock Formation) and passes upward through tidal-flat siltstones (Thomas River Formation) into open-shelf limestones (Guinea Corn Formation). The succeeding Summerfield Group represents a progradational volcanoclastic braid-plain delta complex (Green River, Peckham, and Mahoe River Formation) and is succeeded by a thick succession of ignimbrites (Waterworks Formation). The volcanoclastic sediments and ignimbrites are interpreted to have been shed from a newly emergent volcanic center in eastern Jamaica, possibly the Above Rocks magma chamber. The Kellits Synthem is overlain unconformably by the limestones and clastics of the middle Eocene Yellow Limestone Group. This unconformity is interpreted to represent the initiation of northeast-southwest-directed extension that saw the formation of the Wagwater Trough in eastern Jamaica.

1125. **Mitchell, Simon F., and Gavin C. Gunter.** “Biostratigraphy and Taxonomy of the Rudist *Chiapasella* in the *Titanosarcolithes* Limestones (Maastrichtian) of Jamaica.” Cretaceous Research

(2002): 473-87. <http://www.idealibrary.com>. **Refereed**

The taxonomy of the radiolitid rudist *Chiapasella* Müllerried from the *Titanosarcolites* Limestones of Jamaica is revised based on the bed-by-bed collection of specimens from the Central and Maldon inliers. Two species are recognised: *Chiapasella radiolitiformis* Trechmann and *C. trechmanni* sp. nov. *C. radiolitiformis* is characterised by usually one or more costae (two or more infolds) in the interband, by the relatively narrow ventral band Vb, and by a costal ornamentation of strong growth lines and subsidiary vertical striations. *C. trechmanni* is characterised by the usual presence of no costae (one infold) in the interband, by the relatively wide Vb, and by a costal ornamentation dominated by vertical striations rather than horizontal growth lines. Two zones are recognised in the *Titanosarcolites* Limestones, a lower zone with *C. radiolitiformis* (B and Middle C Beds of the Central Inlier) and an upper zone with *C. trechmanni* (D and lower F Beds of the Central Inlier; Maldon Limestone, Popkin Shales and Vaughansfield Limestone of the Maldon Inlier).

1126. ——. “First Record of the Rudist Bivalve *Mitrocaprina Tschoppi* (Palmer) From the Maastrichtian of Jamaica.” Caribbean Journal of Science 40.3 (2004): 392-96.

http://caribjsci.org/dec04/40_392-396.pdf. **Refereed**

The large plagiptychid rudist bivalve *Mitrocaprina tschoppi* (Palmer) is recorded from the Guinea Corn Formation (Late Maastrichtian) of central Jamaica. This is the first record of this species outside of Cuba. *M. tschoppi* occurs in rhythm D6 of the Guinea Corn Formation, *Macgillavryia* Bed 1, together with a rudist assemblage including *Praebarrettia sparcilirata* (Whitfield), *Macgillavryia nicholasi* (Whitfield), *Chiapasella trechmanni* Mitchell & Gunter, *Plagiptychus zansi* Chubb, *Titanosarcolites* sp.; *Titanosarcolites* cf. *alatus* Chubb and *Antillocaprina* cf. *occidentalis* (Whitfield). The pallial canals of the Jamaican specimens are identical to the Cuban material, but the Jamaican specimens are larger (about one and a half times the size).

1128. **Mitchell, Simon F., Thomas A. Stemann, Donovan Blissett, Ian C. Brown, Winston O'Brian Ebanks, Gavin C. Gunter, David J. Miller, Andrew G. Pearson, Byron S. Wilson, and Winston A. Young.** “Late Maastrichtian Rudist and Coral Assemblages From the Central Inlier, Jamaica: Towards an Event Stratigraphy for Shallow-Water Caribbean Limestones.”

Cretaceous Research 25 (2004): 499-507. **Refereed**

The lithological succession of the Guinea Corn formation in the slippery rock river, central Jamaica, comprises 91 m of limestones and subsidiary mudstones. The biostratigraphic distribution of rudist bivalves and corals demonstrates that the succession of biostratigraphic markers is consistent with the previously standard Guinea Corn formation succession in the Rio Minho between Grantham and Guinea Corn, central Jamaica. Additionally, the slippery rock river succession shows the boundary between the *Chiapasella radiolitiformis* and *C. trechmanni* zones that has not previously been documented. The marker horizons are also consistent with major facies changes within both sections, demonstrating that both lithological changes and biostratigraphic markers are synchronous within the limestones successions of central Jamaica. This may prove to be a valuable tool for stratigraphic correlation elsewhere in Jamaica and within the Antillean region.

1130. **Robinson, Edward.** “Changes Along the Coast of Vere, Jamaica, Over the Past Two Hundred Years: Data From Maps and Photographs.” Quaternary International 120 (2004): 153-61. **Refereed**

Analysis of air photographs and maps indicates complex patterns of shoreline changes along the south coast of Vere, Jamaica, between the mouths of the Rio Minho and Milk River. These include up to half a kilometre of shore-normal coastal recession between 1941 and 1991, the largest known shoreline change in Jamaica over the past 60 years. Previously, the coastline had been prograding seawards from a low cliff cut into the Rio Minho alluvial fan, in the process constructing a shore-parallel ridge and lagoon complex. The cliff itself is evidence of earlier coastal erosion. Maps published in 1804 and 1885 confirm the mobility of this coastline in historical times. They suggest that the more easterly complex of shore-parallel lagoons was constructed prior to about 1880, while the more recent, westerly beach ridges developed, at least partly, from progressive destruction of the lagoon complex, following a change in orientation of the Rio Minho mouth in the late 19th Century. Photographs of 1999 indicate the onset of accretion, probably resulting from the gradual onshore movement of massive quantities of sediment deposited off the Rio Minho mouth during the extreme flood event of 1986 and several lesser events in 1988 and the 1990s.

1131. ——. “Upper Paleogene Larger Foraminiferal Succession on a Tropical Carbonate Bank, Caribbean Region.” From Greenhouse to Icehouse: The Marine Eocene-Oligocene Transition. Editors D. R. Prothero, L. C. Ivany, and E. A. Nesbitt. New York: Columbia University Press, 2003. 294-302.

1132. ——. “Zoning the White Limestone Group of Jamaica Using Larger Foraminiferal Genera: A Review and Proposal.” Cainozoic Geology 3.1-2 (2004): 37-75. **Refereed**

A scheme of biozones with at least local application, is proposed for strata of the White Limestone Group of Jamaica, based on larger benthic foraminiferal genera. Four zones, the *Asterocyclina*, *Eulepidina*, *Miogypsina* and *Amphistegina* zones, extend through the Eocene, Oligocene, Lower Miocene, and Middle Miocene and higher horizons, respectively. The *Asterocyclina* Zone is divided into four subzones, three of Middle Eocene and one of Late Eocene age. The lowest of these includes strata of the Yellow Limestone Group, but only doubtfully of the White Limestone Group in central Jamaica. The *Eulepidina* Zone is divided into three subzones, the *Miogypsina* Zone into two. The *Amphistegina* Zone contains one subzone, the *Nummulites* Subzone, which extends through the upper part of the White Limestone Group. The higher part of the *Amphistegina* Zone is not divided. Further subdivision within some subzones is indicated, but not formalised. Correlation of the zones and subzones with larger foraminiferal genera of the platform interior still presents problems for Oligocene and Miocene horizons. Assemblages containing *Praerhapydionina delicata* are assigned to the Oligocene. Those with archaiasinids, resembling *A. kirkukensis*, are found near the Oligo-Miocene boundary, and may span the stratigraphic interval marked by the occurrence of *Heterostegina (Vlerkina) antillea*. The ‘*Amphisorous matleyi*’ fauna of earlier workers appears to be wholly of Miocene age.

1135. **Stemann, Thomas A.** “Reef Corals of the White Limestone Group of Jamaica.” Cainozoic Research 3.1-2 (2004): 83-107. **Refereed**

Sedimentary rocks of the White Limestone Group of Jamaica were deposited in a range of shallow-to-deep-water marine settings from the Middle Eocene to Middle Miocene. Horizons rich in scleractinian corals occur throughout this lithologic unit. The present study, using large, new collections (>2,000 specimens) and museum specimens, recognizes 98 scleractinian species in 42 genera in the White Limestone Group. Thirty-six of these species have not been previously described in the literature. From the Middle to Upper Eocene, eleven species are reported from the Troy Formation, twelve from the upper Middle Eocene Swanswick Formation and eleven species from the Late Eocene Somerset Formation. In the Moneague Formation, fifty-two species are recorded from the lower part of the Upper Oligocene succession in units formerly mapped as the Browns Town Formation. Also, in the uppermost Oligocene of the Moneague Formation, sixty-four coral species are reported from rocks formerly mapped as the Newport Formation. An additional fifteen species are reported from the Early Miocene portions of the Montpelier Formation. In addition to scleractinian corals, a stony octocoral species (*Parapolytremacis* sp.) is found in the Upper Oligocene of the Moneague Formation, and at least two species of *Millepora* (class Hydrozoa) are recorded from the Eocene and Oligocene portions of the White limestone Group. Coral assemblages from the Eocene of the White Limestone Group are largely dominated by scattered, thinly branched and free-living corals, while Late Oligocene assemblages contain a diverse group of large massive, plate-shaped and branched corals in a system of patch reefs and coral carpets. The early Miocene assemblage represents a possible deeper forereef community transported into deep water sediments in an olistostromic block. The total number of species found exceeds that known from any other single region or lithologic unit in the Caribbean Eocene through Miocene.

Strontium isotope ratios ($^{87}\text{Sr}/^{86}\text{Sr}$) in pristine low-Mg calcite of shells of rudist bivalves from the *Titanosarcolithes* limestones exposed in the Central, Maldon, and Marchmont inliers of Jamaica indicate that species-rich rudist-coral associations persisted into the latest Maastrichtian (66-65 Ma). This finding contradicts the currently accepted hypothesis of stepwise extinction of rudist bivalves in the middle Maastrichtian and argues for a catastrophic, impact-related demise of Caribbean Cretaceous reefal ecosystems at the Cretaceous-Tertiary boundary.

Jamaica, with its overfished marine resources, has become a major tilapia producer in Latin America led by a small number of large farms practicing tilapia culture with considerable commercial success. Across the country, however, aquaculture is typically practiced by a large number of small - scale fish farmers who own less than 1.0 ha of land. Production is constrained by lack of credit, finite land space and suitable soil type, but larger existing aquaculturists are expanding further for overseas markets. Inspired by pioneering tilapia fish culture demonstration projects funded by the USAID and the government of Jamaica, fish culture production rose from a few hundred kg of *Oreochromis niloticus* in 1997, to about 5000 t of processed fish mainly red hybrid tilapia, in 2000. Most of this quantity was exported to Europe and North America.

Synthesis of a BQQ-neomycin conjugate is reported. The conjugate combines two ligands, one known to intercalate triplexes (BQQ) and another known to bind in the triplex groove (neomycin). The conjugate stabilizes T·A·T, as well as mixed base DNA triplex, better than neomycin, BQQ, or a combination of both. The conjugate selectively stabilizes the triplex (in the presence of physiological salt concentrations), with as little as 4 M of the ligand leading to a TC. Competition dialysis studies show a clear preference for the drug binding to triplex DNA/RNA over the duplex/single strand structures. Modeling studies suggest a structure of neomycin bound to the larger W-H (Watson-Hoogsteen) groove with BQQ intercalated between the triplex bases.

Kingston Harbour, Jamaica has a history of eutrophication due to nutrient loadings emanating from the city of Kingston. In this study a two dimensional, numerical, hydro-dynamic model of the harbor is used to assess the impact of coastal development at the western end of the harbor and on the evolution of this eutrophication. The model shows that the development did not materially affect the flushing of the harbor; therefore the rapid increase in eutrophication since 1970 must be linked to concurrent population pressure. However, the coastal modification has altered the circulation pattern within Hunts Bay and has reduced the exchange between Hunts Bay and the remainder of Kingston Harbour. Increased siltation and further eutrophication within Hunts Bay are predicted as the impact of the modification. The model was also used to investigate the feasibility of aiding the flushing of the harbor by adding a second entrance. The model showed that such an opening is likely to have negligible impact on the present flushing time.

1157. **Buddo, Dayne St. A., Russell D. Steele, and Emma Ranston D'Oyen.** “Distribution of the Invasive Indo-Pacific Green Mussel, *Perna Viridis*, in Kingston Harbour, Jamaica.” Bulletin of Marine Science 73.2 (2003): 433-41. **Refereed**

In February 1998, green mussels were first observed during the collection of mangrove roots from Kingston Harbour on the south coast of Jamaica by researchers at the University of the West Indies, Mona. Preliminary observations of its morphological characteristics identified the mussel as *Perna viridis*, and this was confirmed by reference to the retractor muscle scars of the inside of the shells and ultimately by chromosome number. Prior to the first sighting in Jamaica, *P. viridis* was seen in Trinidad (1990), and subsequently in Tampa Bay, Florida (1999). A preliminary survey of 29 random sites was carried out in July 1999, which revealed that the mussel had established itself at numerous sites around the Harbour. Ten of these sites were monitored monthly for one year from February 2000 to January 2001 for mussel density, physicochemical parameters, suspended solids, microalgae, and gut contents. Densities varied throughout the year and appeared to be affected by salinity, substrate availability and removal by persons. Analysis of the gut contents of several of these mussels revealed the presence of four species of toxic microalgae, as well as a large amount of organic material. Further studies aimed at following the spread of this invading species are in progress.

Ahmad, and Dennis Gonsalves.** “Biological and Molecular Characterization of Papaya Ringspot Virus Isolated From Papaya Orchards of Different Locations in Jamaica.” Jamaican Journal of Science and Technology 14 (2003): 58-66. **Refereed**

Papaya ringspot virus type-p (PRSV) may have been present in Jamaica as early as 1929. However, it has only recently become a serious threat to papaya production in the island. Both newly established commercial orchards and traditional papaya growing regions of the island are plagued with PRSV. In this study the diversity of PRSV from four locations of the major papaya producing areas in Jamaica was examined to assist in the development of transgenic papaya for the control of the disease across the island. Serology and host range confirmed that the virus samples collected were type-p. Moreover, the host range examined showed no differences in pathogenicity either in symptom expression or in the rate of symptom development. Reverse transcriptase-polymerase chain reaction was used to amplify the coat protein genes of the virus samples. Comparative restriction fragment length polymorphism (RFLP) analyses did not differentiate between samples from the four locations; all gave similar RFLP patterns suggesting low variability within a location and between the four locations examined. The coat protein gene of one of the samples was sequenced. The Jamaican isolate shares 90.2 to 94% amino acid similarities with type-p strains from the Caribbean, the Americas, and Australia. Other isolates are to be cloned and similarly sequenced, however, it appears that transgenic papaya resistant to Jamaican PRSV isolates should be obtained using viral coat protein genes.

1163. **Dunbar, Francine N., and Mona K. Webber**. “Zooplankton Distribution in the Eutrophic Kingston Harbour, Jamaica.” Bulletin of Marine Science 73.2 (2003): 343-59. **Refereed**

The purpose of this study was to describe the spatial distribution of zooplankton relative to water quality throughout Kingston Harbour. Routine sampling was conducted monthly at 24 stations in the harbor over a 15- month period. In total, 73 different taxa were identified of which the copepods were most important (38 species). The outer harbor region showed the greatest number of species, while the lowest diversity was recorded at Hunts Bay and in the Upper basin region of Kingston Harbour. Mean abundances for the area were high and ranged from a minimum of 3663 animals m⁻³ in Hunts Bay, to a maximum of 80,464 animals m⁻³ in the Inner harbor zone at station 8. Results of the zooplankton community similarity index (PSC), using station 4 (located within the Upper basin) as the ‘home’ or focal station, pointed to the existence of three groups of stations in Kingston Harbour: Upper basin (stations 1-6), Inner harbor (stations 7-15) and Outer harbor (stations 16-23). Hunts Bay (station 24) was not included in any of these groups. Dendrograms using mean Euclidean distance indicated similar groups. These groups of stations could also be identified by dominance of individual species. *Temora turbinata* was dominant in the Upper basin group (stations 1-6), *Lucifer faxoni* and *Penilia avirostris* in the Inner harbor group (stations 7-15), *Paracalanus crassirostris* in the Outer harbor group (stations 16-23), and *Acartia tonsa* in Hunts Bay (station 24). Therefore, it may be more reliable to distinguish the zones in Kingston Harbour on the basis of the zooplankton community composition and species dominance, rather than simply on the basis of abundance and diversity. However, the low diversity (indicated by number of species) and low abundances identified Hunts Bay as the most polluted area of Kingston Harbour.

1164. **Ellis-Tabanor, M., and Eric J. Hyslop**. “Effect of Sublethal Concentrations of Endosulfan on Growth and Fecundity of Two Species of Snails.” Bulletin of Environmental Contamination and Toxicology 74 (2005): 1173-78. **Refereed**

Endosulfan (Thiodan 35 EC) is an organochlorine, cyclodiene insecticide, [6,7,8,9,10-hexachloro-1,5,5a,6,9,9a-hexahydro-6,9,-methano-2,4,3-benzodioxathiepine-3-oxide (Rao and MURty 1982)], which is currently registered for use on coffee in Jamaica to control the coffee pest, *Hypothenemus hampei* Ferrari (Pesticide Control Authority,

Jamaica - Personal Communication). It is known to have entered several Jamaican rivers and streams through runoff from coffee farms (Mansingh et al. 1995). Endosulfan is recorded as having adverse effects on the density, growth and reproduction of aquatic organisms (IPCS 1984; Muirhead-Thomson 1987; Hassal 1990; Naqvi and Vaishnavi 1993; Raloff 1998). Two prosobranch snails, *Melanoides tuberculata* and *Thiara granifera* (Family : Thiariade) are common in Jamaican rivers, streams and ponds. Both species are parthenogenetic and viviparous (Beery and Kadri 1974; Dudgeon 1986), and both are introduced into Jamaica. Both species are readily available, easy to rear under laboratory conditions and can tolerate frequent handling. Very little information is available on the toxicity of endosulfan to snails (IPCS 1984; Muirhead-Thomson 1987). This study investigated the impact of sub-lethal concentrations of endosulfan on growth and fecundity of *Melanoides tuberculata* and *Thiara granifera* under laboratory and field conditions.

1166. **Fermin, Gustavo, Paula F. Tennant, Carol Gonsalves, David Lee, and Dennis Gonsalves.** “Comparative Development and Impact of Transgenic Papayas in Hawaii, Jamaica and Venezuela.” Transgenic Plants: Methods And Protocols 286 (2004): 399-430.

<http://www.humanapress.com/ChapterDetail.pasp?isbn=1-59259-827-7&ccode=1-59259-827-7:399&returntoisbn=>. **Refereed**

The authors present data concerning the creation of transgenic papayas resistant to Papaya ringspot virus (PRSV) and their adoption by three different countries: USA (e.g. Hawaii), Jamaica and Venezuela. Although the three sets of transgenic papayas showed effective resistance to PRSV, adoption rate in each country has varied from full exploitation in Hawaii, to aggressive testing but delay in deregulating of the product in Jamaica, to rejection at an early stage in Venezuela. Factors that contributed to the rapid adoption in Hawaii include a timely development of the transgenic product, PRSV causing severe damage to the papaya industry, close collaboration between researchers and the industry, and the existence of procedures for deregulating a transgenic product. In Jamaica, the technology for developing the initial field-testing of the product progressed rather rapidly, but the process of deregulation has been slowed down due to the lack of sustained governmental efforts to complete the regulatory procedures for transgenic crops. In Venezuela, the technology to develop and greenhouse test the transgenic papaya has moved abreast with the Jamaica project, but the field testing of the transgenic papaya within the country was stopped very early on by actions by people opposed to transgenic products. The three cases are discussed in an effort to provide information on factors, other than technology, that can influence the adoption of a transgenic product.

1167. **Goodbody, Ivan.** “The Ascidian Fauna of Port Royal, Jamaica I. Harbor and Mangrove Dwelling Species .” Bulletin of Marine Science 73.2 (2003): 457-76. **Refereed**

The near-shore environment of Port Royal, Jamaica and its adjacent mangrove ponds is described. Thirty-nine species of ascidian in 23 genera are listed as occurring in this area and brief notes and descriptions of their distribution and habitat preferences are provided. This fauna is compared with that occurring in other localities and it is concluded that the ascidian fauna of Port Royal is representative of faunal communities occurring in near-shore lagoonal environments in the Caribbean. The need to conserve Port Royal’s biological heritage is addressed.

1169. —. “Kingston Harbour, Jamaica: An Overview.” Bulletin of Marine Science 73.2 (2003): 249-55. **Refereed**

Kingston Harbour is often considered to be one of the finest natural harbours in the world. Comprised of two regions—the outer Harbour and the inner Harbour, the Kingston Harbour offers numerous opportunities in the areas of scientific research and development. This article provides a synopsis of the Kingston Harbour by topographical formation, its evolution and that of the surrounding areas that impacted its natural occurrences as well as those that have benefited from the Harbour. These uses of the harbour are highlighted in addition to the factors of pollution that have contributed to its degradation.

1170. —. “Port Royal as a Focal Point for Marine Biodiversity in Jamaica.” Jamaican Journal of Science and Technology 15 (2004): 37-53. **Refereed**

A specially protected area, The Port Royal and Palisadoes Protected Area, was gazetted in October 1998, to provide protection for both the biological and archaeological heritage which exists in the environs of Port Royal. A previous synthesis of the biological heritage, completed just prior to declaration of the protected area, is considered not to have captured all the historical information gathered by researchers at two marine laboratories, one at Port Henderson in the late 19th century and the other at Port Royal from 1955 to present. This literature is reviewed and it is shown that there is a species rich diversity of plants and animals in the marine environment around Port Royal. It is also shown that Port Royal is the *type locality* for at least 47 species of marine invertebrate animal. Jamaica is a signatory to the UN Convention on Biodiversity which binds the State to document and conserve its biological diversity. It is suggested that in keeping with this mandate an attempt should be made to create a National Database on Marine Biodiversity, bearing in mind that such a database might ultimately have to accommodate over one million entries.

1171. **Green, Sean O., and Dale F. Webber.** “The Effects of Varying Levels of Eutrophication on Phytoplankton and Seagrass (*Thalassia Testudinum*) Populations of the Southeast Coast of Jamaica.” Bulletin of Marine Science 73.2 (2003): 443-56. **Refereed**

Being stationary, seagrass populations respond markedly and cumulatively to continued eutrophication over both time and space. Six seagrass meadows located within and near the eutrophic Kingston Harbour were investigated from October 1995 to June 1996 to determine the effects of increased eutrophication on seagrass population dynamics. The stations were sited at Fort Augusta, Old Coal Wharf (eutrophic, harbour sites), Hellshire coast (mesotrophic) and Port Royal Cays (oligotrophic). Aerial productivity, leaf turnover rate, leaf area, shoot density and total biomass of *Thalassia testudinum* were assessed during the period. In addition, the water quality at all the sites was monitored, using phytoplankton biomass as the primary index of water quality. These data were supplemented with water temperature, salinity, dissolved oxygen content, nutrients (nitrates + nitrites and phosphates), and light extinction coefficient data at these sites. Although there were no significant differences in labile nutrient data at six sites, the significant difference in phytoplankton biomass confirmed previous observations of a range of water qualities. Water quality ranged from the eutrophic Kingston Harbour ($>2.0 \text{ mg m}^{-3} \text{ chl a}$), to mesotrophic Hellshire Bays ($0.57 \pm 0.02 \text{ mg m}^{-3} \text{ chl a}$), and the oligotrophic Port Royal Cays ($0.21 \pm 0.01 \text{ mg m}^{-3} \text{ chl a}$). *Thalassia testudinum* populations exhibited an increase in leaf productivity rates ($3.64 \pm 0.39 \text{ g dwt m}^{-2} \text{ d}^{-1}$ at South East Cay to $5.46 \pm 1.11 \text{ g dwt m}^{-2} \text{ d}^{-1}$ at Old Coal Wharf) and an increase in leaf area ($11.64 \pm 1.2 \text{ cm}^2$ at South East Cay to $22.85 \pm 2.87 \text{ cm}^2$ at Fort Augusta) with increasing eutrophication. Conversely, there was a reduction in shoot density ($917.25 \pm 199.92 \text{ m}^{-2}$ at South East Cay to $459.62 \pm 65.35 \text{ m}^{-2}$ at Old Coal Wharf) and total biomass ($972.68 \pm 88.39 \text{ g dwt m}^{-2}$ at Rackhams Cay to $406.24 \pm 62.16 \text{ g dwt m}^{-2}$ at Fort Augusta) with increasing eutrophication stress. Comparisons with previous studies from ten years before indicated that *Thalassia testudinum* shoot biomass and density decreased at all times, while leaf productivity rates increased at oligotrophic sites and decreased at eutrophic sites during this period.

1172. **Harvey, Guy C. McN., Ivan Goodbody, and Karl A. Aiken.** “The Artisanal Thread Herring Fishery of Kingston Harbour: A Review.” Bulletin of Marine Science 73.2 (2003): 421-32. **Refereed** Eight species of pelagic clupeid fishes contribute to a small artisanal fishery in Kingston Harbour. This paper reviews studies of this fishery carried out over a period of three years between 1980-1983. The thread herring *Opisthonema oglinum* contributes the largest biomass of catch in this industry, which may have amounted to as much as 250 t yr⁻¹ under favorable conditions. Evidence from a more recent study suggests that catches may have declined in recent years. Sustainability of the fishery is dependent on high levels of eutrophication supported by continued pollution of the harbour environment by domestic and industrial wastes. Consumers of these fish stocks are residents of poverty stricken areas of Kingston who are thus vulnerable to any contaminants entering the food chain from industrial or agricultural sources.

1178. **McDonald, Kerrine O., Dale F. Webber, and Mona K. Webber.** “Mangrove Forest Structure Under Varying Environmental Conditions.” Bulletin of Marine Science 73.2 (2003): 491-506. **Refereed**

Vegetation assessments were carried out in three mangrove forests undergoing different levels of anthropogenic stress and varying environmental factors. These forests were in Hunts Bay, Fort Rocky Lagoon (part of the Port Royal mangroves on the south shore of Kingston Harbour), and Wreck Bay (Hellshire). The vegetation assessments included the determination of species composition, floristics, and leaf litter production of the mangrove trees. Selected environmental and biological conditions were also investigated at each site. The hypothesized gradient of environmental factors, eutrophication and disturbance was Hunts Bay > Fort Rocky Lagoon > Wreck Bay. With the exception of light on the forest floor, the soil and water column parameters were all significantly different among

sites, but the values did not always follow the expected environmental gradient. For example, nitrate/nitrite values were maximum at Wreck Bay (34.4 μM), followed by Hunts Bay (12.41 μM) and Fort Rocky Lagoon (10.0 μM), and phosphates ranked with maximum at Fort Rocky Lagoon (9.69 μM), then Hunts Bay (4.41 μM) and Wreck Bay (1.24 μM). Of the vegetation characteristics, only average leaf litter production and percentage cover were significantly different among sites, with a ranking similar to the hypothesis (i.e. Hunts Bay > Fort Rocky Lagoon > Wreck Bay). The most important factors influencing the distribution of productivity and percentage cover among forests were soil salinity, soil NO_3 , especially the nitrate to phosphate ratio, soil moisture content and soil temperature with R^2 values of 0.77 for litter production and 0.64 for percentage cover. Other factors such as diameter at breast height and tree height were not significantly different among forests and showed a weak relationship with edaphic factors. Overall results indicated that the forests were very different with respect to physico-chemical and edaphic factors, and there was a clear gradient of eutrophication. However, the effect of anthropogenic stress and varying environmental conditions is most reliably demonstrated in the productivity and percentage cover of the forests.

1179. **Mendes, Judith M.** "Timing of Skeletal Band Formation in *Montastraea Annularis*: Relationship to Environmental and Endogenous Factors." Bulletin of Marine Science 75.3 (2004): 423-37. **Refereed**

The timing of density band formation, the seasonal growth rate, and the relationship of dense band formation to temperature, light, rainfall, growth rate, polyp tissue depth, and reproduction were determined in 15 Jamaican *Montastraea annularis* (Ellis and Solander, 1786) colonies by means of a long-term field study. The time and duration of high density (HD) band formation was from late August to early October. HD band formation occurred when monthly skeletal extension rates were lowest and gonads were largest. The strong correlations between HD band formation and skeletal extension rate, the inconsistent relationships between HD band formation and light intensity in the literature, and the absence of any significant correlation between HD band formation and polyp tissue depth, have led us to propose that density band formation is related primarily to changes in skeletal extension rate. Additionally, the strong correlations observed between gonad size and both HD band formation and skeletal extension support the premise that HD bands in *M. annularis* result from the diversion of resources to reproduction. A hypothesis of HD band formation based on the diversion of resources from growth to reproduction might also explain some of the variations in HD band formation time found in the literature as well as the absence of clear density bands in some species.

1180. **Mendes, Judith M., and Woodley D. Jeremy.** "Timing of Reproduction in *Montastraea Annularis*: Relationship to Environment." Marine Ecology Progress Series 227 (2002): 241-51. The timing of reproduction was investigated in 15 colonies of *Montastraea annularis* located on the Port Royal Cays, Jamaica. Spawning occurred between days 6 and 8 after August's and/or September's full moon. In the 14 week prior to spawning, mean total gonad size increased from 0.30 ± 0.17 to $34.38 \pm 13.20\%$ of the polyp cross-sectional area. Gonad size was significantly correlated with temperature and light intensity, but was correlated with photoperiod or rainfall. Spawning occurred in the month prior to the period of heaviest rainfall, when temperatures were at their maximum. A meta-analysis of spawning time and climate conditions at 19 other geographical locations also showed that spawning occurs in those periods without rainfall in which temperatures are warmest. The data presented here suggest that temperature is not the only environment variable controlling the annual timing of coral spawning. Rather, the time of coral spawning is controlled by a combination of temperature and rainfall.

1185. **Persad, Gale, Russell R. Hopcroft, Mona K. Webber, and John C. Roff.** “Abundance, Biomass and Production of Ctenophores and Medusae Off Kingston, Jamaica.” Bulletin of Marine Science 73.2 (2003): 379-96. **Refereed**

The species composition, abundance, biomass and production of ctenophores and medusae were determined fortnightly from September 1992 to December 1993 in eutrophic waters at the mouth of Kingston Harbour and mesotrophic waters off Lime Cay, Jamaica. The three species of ctenophores, *Bolinopsis vitrea*, *Beröe ovata* and *Ocyropsis crystallina*, occurred at both stations, together averaging 0.82 m^{-3} in the harbor and 0.60 m^{-3} at Lime Cay. The ten genera of medusae identified were common to both locations, but their abundances differed considerably, averaging 13.5 m^{-3} in the harbor and 3.0 m^{-3} at Lime Cay. In the harbor, *Eutima gracilis*, *Liriope tetraphylla*, *Ectopleura dumortieri*, *Cladonema* sp. and *Clytia* sp. all contributed variably to the community without clear seasonality. At Lime Cay, the medusae were equally dominated by *Clytia* sp. and *Liriope tetraphylla*. Community biomass was estimated using size-mass relationships established for each of the ctenophores, and the morphologically representative medusae: *Eutima gracilis*, *Liriope tetraphylla* and *Clytia* sp. Ctenophore biomass averaged $663 \text{ mg wet-weight m}^{-3}$ (18 J m^{-3}) at the mouth of Kingston Harbour and 363 mg m^{-3} (8.4 J m^{-3}) at Lime Cay, with *Bolinopsis vitrea* dominant at both sites. Biomass of medusae at the mouth of Kingston Harbour was 605 mg m^{-3} (94 J m^{-3}), dominated by *Eutima gracilis* and *Liriope tetraphylla*. The biomass of the medusae at Lime Cay was 25 mg m^{-3} (4.0 J m^{-3}), dominated solely by *Liriope tetraphylla*. Production was estimated using growth rates experimentally determined for *Bolinopsis vitrea*, *Eutima gracilis*, *Liriope tetraphylla*, and *Clytia* sp. *Bolinopsis vitrea* was the most productive ctenophore at both sampling stations, while for the medusae, *Eutima gracilis* dominated the production at the mouth of Kingston Harbour and *Liriope tetraphylla* dominated at Lime Cay. The greater proportion of the production of these gelatinous carnivore communities was attributable to the ctenophores in terms of wet-weight (52 and 77%), but not in terms of energetic production (15 and 32%). Together their annual production at the mouth of Kingston Harbour was $155 \text{ g m}^{-3} \text{ yr}^{-1}$ ($13.9 \text{ kJ m}^{-3} \text{ yr}^{-1}$), while that at Lime Cay was $63 \text{ g m}^{-3} \text{ yr}^{-1}$ ($3.5 \text{ kJ m}^{-3} \text{ yr}^{-1}$). Such production would require 36% or more of the combined copepod and larvacean production at these locations.

1186. **Ranston, Emma R., Rose-Marie A. Simmonds, and Dale F. Webber.** “The Phytoplankton Distribution in Kingston Harbour, Jamaica.” Bulletin of Marine Science 73.2 (2003): 325-42. **Refereed**

The phytoplankton community composition, abundance and size-fractionated biomass (chlorophyll a) along with various physical and chemical parameters were assessed in Kingston Harbour, Jamaica. Monthly sampling was conducted at 31 stations, each with two sampling depths throughout the harbor between December 1993 and February 1995. The objectives of this study were to characterize the phytoplankton community of Kingston Harbour, to use this community structure to identify possible horizontal zonation and vertical stratification of the water mass in the harbor, and compare this with previous findings. Results suggested that the water mass of the harbor shows temporary vertical stratification during the wet seasons into a less saline surface layer and a more saline deep layer as defined by significant differences in the mean total phytoplankton biomass and cell abundance. Mean number of cells per liter in surface waters during the wet season ranged from 7×10^5 to 10×10^7 cells L^{-1}

compared to lower values for deep water that ranged from 3×10^5 to 9.3×10^7 cells L^{-1} . Values for mean total biomass in surface waters during the wet season ranged from 1.01-24.5 mg chl $a\ m^{-3}$, as compared to lower values in deeper water, which ranged from 0.56-22.1 mg chl $a\ m^{-3}$. Determination of stratification using the phytoplankton community was difficult to assess since most phytoplankton exhibit the tendency to sink through the water column while motile forms exhibit vertical migration between surface and deeper waters. Phytoplankton biomass was, however, very reliable for defining horizontal zones across the harbor. This was true for both surface and deep waters at each station in the harbor. Total and size fractionated chlorophyll a in surface waters indicated three zones; one being the surface water layers of the upper basin and the inner harbor, the second being the outer harbor, and the surface water layers of Hunts Bay formed the third zone. However, multiple range tests conducted on deep water chlorophyll a data defined four zones in the harbor: the deep water layers of the upper basin, the inner harbor, the outer harbor, and Hunts Bay, respectively. Dissolved oxygen and NO_3-N+NO_2-N concentrations supported the horizontal zonation pattern defined by the phytoplankton community.

1187. **Ranston, Emma R., and Dale F. Webber.** "Phytoplankton Distribution in a Highly Eutrophic Estuarine Bay, Hunts Bay, Kingston Harbour, Jamaica ." Bulletin of Marine Science 73.2 (2003): 307-24. **Refereed**

The phytoplankton community composition, abundance and size fractionated biomass (chlorophyll a) along with various physical, chemical and biological parameters were assessed monthly from December 1993 to February 1995 at two sampling depths at each of nine stations throughout Hunts Bay, Jamaica. The objective of the study was to investigate the distribution of the phytoplankton community within Hunts Bay in order to identify the major sources of stratification and ecological zones of Hunts Bay. Results indicated highly significant differences between surface and deep waters in physical, chemical and biological parameters, particularly during the wet season. This suggested a stratification, or vertical zonation of the Bay into two layers, an upper 0.5 m deep, fresh-brackish water (0-18 salinity) layer, and a deeper 0.5-2.5 m, more saline (24-30) layer. Horizontal variation in physical variables from station to station was low; thus, these variables were of little value in designating horizontal zonation of the Bay. Chemical and biological variables, however, were highly variable and along with community analyses, were quite valuable in designating the horizontal zones of the surface and deep-water layers of the Bay into four general regions: the North Bay, Middle Bay, South Bay and Outer Bay. Both surface and deep-water layers had the same zonation pattern and each zone (except for the Outer Bay) was dependent on, and influenced by, the nearest fresh water inflows. The Outer Bay was influenced more by close proximity to the saline water of Kingston Harbour. At North Bay stations, results of nutrient concentrations ($PO_4 = 0.73\ \mu M$), phytoplankton abundance (7.5×10^7 cells L^{-1}), and biomass (18.69 mg chl $a\ m^{-3}$) were all significantly (MANOVA, $P < 0.0001$, $df = 9$) higher compared to the remaining stations of the bay. Therefore, the North Bay was classified as the most eutrophic area of Hunts Bay. There was an eutrophication gradient in the other zones from North to South Bay, followed by the Middle then Outer Bays. This confirms that Sandy Gully and the Duhaney River are the major sources of eutrophication to the Hunts Bay. The Rio Cobre may have significant effect on Hunts Bay; however, the volume of fresh water from this source dilutes the nutrient concentrations and flushes pollutants out of the Bay.

1188. **Robinson, Dwight E., C. Henry, and Ajai Mansingh.** "Ecotoxicity Studies in Jamaican Environment II: Toxicity, Bioaccumulation, Elimination and Tissue Partitioning of Dieldrin by the Shrimp, *Macrobrachium Faustinum*." Environmental Technology 23.11 (2002): 1275-84. **Refereed**

1189. ——. "Toxicity, Bioaccumulation and Tissue Partitioning of Dieldrin by the Shrimp, *Macrobrachium Faustinum* De Sature, in Fresh and Brackish Waters of Jamaica." Environmental Technology 23: 1275-84. **Refereed**

The 2-week no observed effect (NOEC) and lowest observed effect (LOEC) concentrations of dieldrin were determined for *macrobrachium faustinum de sature* in fresh and brackish waters. LOEC 1, 10, 50, 95 values in fresh water were 0.001, 0.003, 0.011 and 0.058 $\mu g\ l^{-1}$, respectively, and in brackish water, 0.00006, 0.00027, 0.00165,

and $0.0172 \mu\text{g l}^{-1}$, respectively. The 96-hr LC_{10} , LC_{50} and LC_{95} values were 0.029, 0.123 and 0.771

$\mu\text{g l}^{-1}$, respectively. It is proposed that NOEC and LOEC be redefined to take into account the percentage of individuals affected, the severity of symptoms and the recovery of poisoned individuals. Two new terms are proposed - Median Observable Effect Concentration (MOEC) for pronounced toxic symptoms in most individuals but mortality in <50%, and Pronounced Observed Effect Concentration (POEC), which inflicts mortality in >50% individuals. Bioaccumulation of dieldrin by *M. faustinum* from surrounding fresh and brackish waters were rapid and fairly uniform for the first 48 h when the bioconcentration equilibrium ($14.4 \pm 0.42 \text{ ng g}^{-1}$ at $0.001 \mu\text{g l}^{-1}$ and $42.5 \pm 1.72 \text{ ng g}^{-1}$ at $0.01 \mu\text{g l}^{-1}$) was achieved. Relative partitioning of residues (ng g^{-1} wet wt.), after 24 h exposure to $0.001 \mu\text{g l}^{-1}$ of dieldrin in fresh water, in the different tissues was hepatopancreas > gonads > gills > large claws > muscle and exoskeleton. Shrimp which had accumulated $10.5 \pm 0.52 \text{ ng g}^{-1}$ dieldrin in fresh and brackish water, eliminated only about 52% of the residues after eight days in uncontaminated water.

Transgenic papayas (*Carica papaya*) containing translatable coat protein (CPT) or nontranslatable coat protein (CPNT) gene constructs were evaluated over two generations for field resistance to Papaya ringspot virus in a commercial papaya growing area in Jamaica. Reactions of R-0 CPT transgenic lines included no symptoms and mild or severe leaf and fruit symptoms. All three reactions were observed in one line and among different lines. Trees of Most CPNT lines exhibited severe symptoms of infection, and some also showed mild symptoms. R-1 offspring showed reactions previously observed with parental R-0 trees; however, reactions not previously observed or a lower incidence of the reaction were also obtained. The transgenic lines appear to possess virus disease resistance that can be manipulated in subsequent generations for the development of a product with acceptable commercial performance.

1201. —. “Transformation of *Carica Papaya* L. With Virus Coat Protein Gene for Studies on Resistance to Papaya Ringspot Virus From Jamaica.” Tropical Agriculture (Trinidad) 79.2 (2002): 105-13.

Translatable and non-translatable versions of the coat protein gene (CO) of a Papaya ringspot virus (PRSV) isolate from Jamaica were used to transform papaya (*Carica papaya* L.) embryos by microprojectile bombardment. One hundred and fifty transgenic calli were obtained, of which 39 were regenerated and established in the greenhouse. Coat protein was detected (75%) by polymerase chain reaction; varying levels of CP ribonucleic acid (RNA) transcript and expression protein were detected by Northern analysis and enzyme-linked immunosorbent assays, respectively. R₀ and R₁ plants were challenged under greenhouse conditions with the homologous PRSV isolate from which the transgene was derived and heterologous isolates from other locations across Jamaica. R₀ plants carrying the translatable CP were highly resistant and more resistant (78%) to inoculation with the homologous PRSV than lines transformed with the non-translatable CP (10%). However, 15% of the latter lines exhibited a recovery phenotype whereby plants appeared to out-grow systemic infection. In the following generation, R₁ plants, carrying either version of the CP, exhibited strong resistance but lower levels of resistance (6-46%) to heterologous PRSV isolates. The results suggest that high, broad-spectrum resistance against PRSV isolates across Jamaica should be attainable in subsequent generations by conventional breeding within and between selected transgenic lines carrying translatable and non-translatable versions of the virus CP gene.

1202. **Tennant Paula F., M. T. Souza, Dennis Gonsalves, M. M. Fitch, R. M. Manshardt, and J. L. Slightom.** “Line 63-1: A New Virus-Resistant Transgenic Papaya .” HortScience 40.4 (2005): 1196-99 .

The disease resistance of a transgenic line expressing the coat protein (CP) gene of the mild strain of the papaya ringspot virus (PRSV) from Hawaii was further analyzed against PRSV isolates from Hawaii and other geographical regions. Line 63-1 originated from the same transformation experiment that resulted in line 55-1 from which the transgenic commercial cultivars, ‘Rainbow’ and ‘SunUp’, were derived. Plants of line 63-1 used in this study consisted of a population from a self-pollinated R-0 bisexual plant. ELISA and PCR tests provided evidence that there are at least two segregating CP loci. To allow for comparison with reactions of the previously reported line 55-1, virus isolates from Hawaii, Brazil, Thailand, and Jamaica were used to challenge seedlings of 63-1. Unlike line 55-1, a significant percentage of inoculated transgenic plants were susceptible to isolates from Hawaii. However, a proportion of plants were resistant to the non-Hawaiian isolates. In contrast, previous work showed that all plants of the hemizygous line 55-1 were susceptible to PRSV isolates from Brazil, Thailand, and Jamaica. Line 63-1,

therefore, presents Hawaii with PRSV-resistant transgenic germplasm that could be used as a source of transgenes for resistance to PRSV isolates within and outside of Hawaii.

1203. **Thompson, Heather P, and Dale F. Webber.** “The Sand Dune Ecology of the Palisadoes, Kingston Harbour, Jamaica.” Bulletin of Marine Science 73.2 (2003): 507-20. **Refereed**

The Palisadoes is a 16 km tombolo forming the south border of the Kingston Harbour, characterized by dune vegetation on the southern windward side and mangrove thickets on the northern leeward side. The coastal vegetation there was investigated and characterized using four transects. Research was limited to the windward side where the little studied sand dune community exists. Vegetation attributes investigated along the transects were species composition, height, percentage vegetation cover, vegetation life form and leaf size class. Environmental parameters and variables assessed were relative humidity, air temperature, wind velocity, light intensity and salt spray. Edaphic parameters assessed were soil temperature, soil moisture, soil salinity, soil nutrient content and organic content. The sand dune community of the Palisadoes exhibits zonation indicated by change in percentage cover, height and species composition. The three zones identified (strand beach, strand dune and strand thorn-scrub) are characterized by different dominant species assemblages. Strand beach zone was characterized by a *Sporobolus sp.*, *Gomphrena sp.* and *Sesuvium sp.* assemblage, the narrow strand dune zone by replacement with a *Capparis* and *Calliandra* assemblage and the strand thorn-scrub by further addition of a dominant *Acacia-cacti* assemblage. The presence of particular zones in each transect was influenced by different climatic and edaphic conditions with salt spray, soil moisture, organic content, and soil water content being important factors. Two endemic species were identified. *Calliandra pilosa* and *Opuntia jamaicensis*, compared with five in a 1953 report. Recent road realignment and widening/resurfacing development as well as environmental theft have increased the pressure on the rare and endemic species found in this sand dune community. Continued vegetation loss could impact on dune stability and integrity of Palisadoes and associated communities within Kingston Harbour.

1208. **Webber, Dale F., and Peter Wilson Kelly.** "Characterization of Sources of Organic Pollution to Kingston Harbour, the Extent of Their Influence and Some Rehabilitation Recommendations ." *Bulletin of Marine Science* 73.2 (2003): 257-71. **Refereed**

Sources of organic pollution to Kingston Harbour were assessed by monthly sampling at 22 rivers, gullies and discharge pipes emptying into the harbor between August 1996 and July 1997. These sources were divided into point and non-point sources and coupled with underground water and industrial flow assessed from 1992 and 1996 data. Organic pollutions signatures were coliform bacteria, total suspended solids (TSS), bio-chemical oxygen demand (BOD), nitrite + nitrate nitrogen and phosphate phosphorous. Sewage is by far the most important contributor of organic pollution to Kingston Harbour, regardless of the signature used. The continuity and concentrations at the outfall of the Greenwich and Western sewage treatment plants render these two areas as the most significant point sources of pollution to the harbor. River flow is the second largest point source of organic pollution to the harbor; the degree of its contribution depending on rainfall since only at high flow does it make major contributions. Poor watershed management, extensive agriculture inputs from few, but large industries, large and growing residential areas and the length of the river creates problems. When the rivers are at low flow, industries and groundwater become major non-point sources of different pollutants. During periods of high water flow the gullies are small, but significant non-point sources of most pollutants. Fifty-five to 70% of the contributions of total suspended solid (TSS) is associated with sewage, while 23-30% is associated with a range of industries. Under high flow conditions, <20% of TSS is associated with the outflow from rivers and gullies, while under low flow conditions, rivers and gullies make no meaningful contribution. Of the contributions of biochemical oxygen demand (BOD), 29-50% is associated with sewage, while 24-40% with industries. Under high flow conditions, 40% of BOD is associated with river outflow, while under low flow conditions, rivers make no meaningful contribution. Of the contributions of nitrate nitrogen, 55-65% is associated with sewage, approximately 30% is associated with ground water and <20% associated with flow from rivers and gullies under high flow conditions. River and gully flow under low flow conditions make no meaningful contribution. Of the contributions of phosphate phosphorous, 75-90% is associated with sewage and <20% associated with high flow conditions from river and gully outflow. At low flow, industries and ground water make no meaningful phosphate phosphorous contribution. Having identified, quantified and ranked the sources of organic pollution to Kingston Harbor, recommendations are suggested for the improvement of the water quality. Among these are a reduction and/or cessation of sewage discharges to the harbor coupled with the use of a predictive hydrodynamic three-dimensional model and an ongoing monitoring program.

1209. **Webber, Dale F., Mona K. Webber, and Doreen D. Williams.** "The Relative Importance of Meteorological Events, Tidal Activity and Bathymetry to Circulation and Mixing in Kingston Harbour, Jamaica." *Bulletin of Marine Science* 73.2 (2003): 273-89. **Refereed**

The objective of the study was to determine the influence of meteorological events (rainfall and wind) as well as tides and bathymetry on the circulation patterns of an enclosed embayment, Kingston Harbour, Jamaica. Current velocity, water temperature and water salinity were assessed at 20 stations within the harbor between December 1993 and February 1995. Meteorological events such as rainfall, wind velocity and tidal periodicity and amplitude were determined in association with routine sampling conducted at the 20 harbor stations. Results indicated that the harbor behaves in a complex manner and is best presented in sectors (zones). The outer harbor has estuarine characteristics and appears to be driven primarily by density/salinity gradients. After heavy rainfall (<65 mm), there is an upper layer (0-5 m deep) of low-salinity water (31-35) flowing quickly (14 cm s^{-1}) out of the harbor, while below 5 m, more saline water (35-36) flows more slowly ($\sim 3 \text{ cm s}^{-1}$) into the harbor. A characteristic of the outer harbor is a deep, but narrow shipping channel where fast currents ($\text{max} = 15 \text{ cm s}^{-1}$) facilitate constant water renewal, thus high water quality. Inner harbor circulation is most affected by tides, but the area also comes under the influence of low salinity water flowing from Hunts Bay as well as high winds from the southeast. Greatest water movement in the inner harbor (18 cm s^{-1}) was achieved when high winds combined with ebb tidal period. The upper basin is primarily affected by winds, which induce horizontal and vertical gyres in the area with little net horizontal movement. Surprisingly, the fastest currents (24 cm s^{-1}) were recorded in the eastern section of the upper

basin; however, this was under conditions of high wind ($>4 \text{ m s}^{-1}$), high rainfall ($>65 \text{ mm}$) and a flooding tidal cycle, which produced the greatest movement throughout the harbor.

1210. **Webber, Mona K.** “Mangrove Lagoons, Zooplankton, Anthropogenic Stress.” Science, Technology and Innovation: UWI Mona Leading the Nation . Mona, Jamaica: University of the West Indies, Mona, 2004. 1-5.

The author summarizes research which identifies the function of mangroves occurring in coastal systems in Jamaica. The water quality in mangals (mangrove dominated areas) is inferred as a means of reversing or reducing degradation in them. The use of anthropogenic stress in mangrove lagoons by using indicators such as zooplankton species provides a basis for the investigations done and reported.

1211. **Webber, Mona K., Dale F. Webber, Emma R. Ranston, Francine N. Dunbar, and Rose-Marie A. Simmonds.** “Changes in Water Quality and Plankton of Kingston Harbour, Jamaica, After 20 Years of Continued Eutrophication .” Bulletin of Marine Science 73.2 (2003): 361-78. **Refereed**

Organic pollution of Kingston Harbour has continued unabated since the first set of comprehensive studies (conducted in the 1970s), which indicated that the area was under stress. The major objective of the most recent study (concluded in the 1990s) was, therefore, to investigate the changes in the water quality and planktonic communities of Kingston Harbour after 20 yrs of continuous nutrient loading. To this end, the abundance, species composition and community structure of the planktonic communities were examined along with water column temperature, salinity, dissolved oxygen, $\text{NO}_2\text{-N} + \text{NO}_3\text{-N}$ and $\text{PO}_4\text{-P}$ concentrations between December 1993 and February 1995 (inclusive). The indices used were similar to those used in the previous characterization and only stations common to both studies and sampled over the entire annual cycle were used for the comparison. All physico-chemical parameters examined (with the exception of light extinction and phosphates) were significantly different between the two studies especially the nitrite + nitrate concentration. Maximum labile $\text{NO}_2\text{-N} + \text{NO}_3\text{-N}$ concentration of $45.3 \mu\text{M}$ and maximum $\text{PO}_4\text{-P}$ concentration of $0.95 \mu\text{M}$ were recorded in the 1994 study compared with values in the 1972 data of $2.02 \mu\text{M}$ and $1.49 \mu\text{M}$, respectively. The increased eutrophic state was indicated by the significantly higher values for mean phytoplankton abundance throughout the harbour compared to 1973 findings. Mean phytoplankton abundance ($29 \times 10^7 \text{ cells L}^{-1}$) for the entire harbor was higher than the previous maximum ($5 \times 10^7 \text{ cells L}^{-1}$). Phytoplankton biomass values were also significantly higher (maximum average = 26.1 mg m^{-3} chlorophyll a) compared to previous findings (maximum average = 16.82 mg m^{-3}) and followed distribution patterns similar to abundance values. The impact of continued eutrophication is further evidenced in a shift in phytoplankton community composition during the 20 yrs from dominance of smaller cells and diatoms to a dominance of larger cells and dinoflagellates. In 1994, mean total numbers of zooplankton for the area were significantly higher and ranged from $3347 \text{ animals m}^{-3}$ in Hunts Bay to $91,905 \text{ animals m}^{-3}$ at station 8, located at the end of the airport runway. This maximum value was 3.6 times the maximum reported in the 1972 study ($25,248 \text{ animals m}^{-3}$), but it was obtained at the same station. In fact, for all zooplankton indices except *Paracalanus spp.* and *Lucifer faxoni* numbers, the values in the present study were all on average between 5.5-1.2 times greater than in 1972. They also followed a similar pattern of distribution. Obvious differences in species distribution were seen in *Temora turbinata* numbers, which in the present study were far more important (on average 52 times greater) than in the earlier study, and in *Penilia avirostris*, which dominated the harbor in the 1972 study. Despite these differences, community diversity between the two periods followed a similar pattern. Therefore, while parameters indicate a worsening of conditions in Kingston Harbour, the pattern of distribution is very similar, suggesting that the areas experiencing the greatest stress remain the same.

A survey was conducted in the Windward Islands of Dominica, St. Lucia, and St. Vincent to obtain information on the characteristics of banana farms, cultural practices adopted, the thriftiness of the crops, the health of the roots, and the abundance of root-parasitic nematodes and fungi. Most farms appeared to be thrifty, irrespective of farm size and duration under cultivation, and apparently received proper crop care. Leaf spot disease control, weed control, and the conditions of the drains needed improvement on some farms. Farmers perceived the unavailability of chemicals, leaf spot disease, and drought as the main production constraints. Other perceived constraints were pest, heavy rainfall, soil texture, slope of land, and lack of labour. Necrotic roots parasitized by micro-organisms occurred on all farms. The most abundant root-parasitic nematode was *Radopholus similis* and the most frequently detected fungus was *Fusarium oxysporum* f. sp. *cubense*. All species of root-inhabiting nematodes and fungi were detected at high and low altitudes. *Helicotylenchus* sp. and *Trichoderma* spp occurred more frequently at altitudes less than 229 m above sea level (asl) than at higher altitudes and the percentage occurrence of *Fusarium* spp and the degree of root necrosis were significantly higher in farms at altitudes higher than 229 m asl than at the lower altitudes. The nematode population densities in roots were positively correlated with the degree of necrosis in roots of suckers at high altitudes in St. Lucia. The information gained from these studies will be useful in the development of integrated control measures.

Restricted permutations are those constrained by having to avoid subsequences ordered in various prescribed ways. A closed set is a set of permutations all satisfying a given basis set of restrictions. A wreath product construction is introduced and it is shown that this construction gives rise to a number of useful techniques for deciding the finite basis question and solving the enumeration problem. Several applications of these techniques are given.

The T-matrix approach as formulated by Pindzola et al. [Phys. Rev. A 62, 062718 (2000)] for calculating the single-differential ionization cross section (SDCD) has been further investigated. Using the “intermediate-energy R-matrix method” to obtain the full scattering wave function needed in the matrix element, we performed several case studies for the Temkin-Poet-wave model of e-H scattering to study the dependence of the results on the box radius and the number of states included. Despite encouraging results before reaching convergence, we conclude that the method will ultimately not yield the correct form of the SDCS but instead will still suffer from unphysical oscillations.

We present an abstraction for pattern formation, called pattern networks, which are suitable for constructing complex patterns from simpler ones in the amorphous computing environment. This work builds upon previous efforts that focused on creating suitable system-level abstractions for engineering the emergence of agent-level interactions. Our pattern networks are built up from combinations of these system-level abstractions, and may be combined to form bigger pattern networks. We demonstrate the power of this abstraction by illustrating how a few complex patterns could be generated by a combination of approximately defined pattern networks. We conclude with a discussion of the challenges involved in parameterising these abstractions, and in defining higher order versions of them.

1220. —. “Amorphous Computing.” Science, Technology and Innovation: UWI Mona Leading the Nation: Mona, Jamaica: University of the West Indies, Mona, 2004.

The author looks at the challenges of computing elements and the use of computing techniques that will enable the control of the global behaviour of such large, inter-connected systems. Hence, the research encompasses the use of amorphous computing systems as a platform for testing different approaches for programming these systems.

1221. —. “Introduction to Amorphous Computing.” Unconventional Programming Paradigms: International Workshop UPP 2004. Editors J. P. Banâtre, P. Fradet, J. L. Giavitto, and O. Michel. Berlin: Springer Verlag, 2005. 99-109.

The study of amorphous computing aims to identify useful programming methodologies that will enable us to engineer the emergent behaviour of a myriad, locally interacting computer elements (agents). We anticipate that in order to keep such massively distributed systems cheap, the elements must be bulk manufactured. Therefore, we must use a conservative model in which the agents run asynchronously, are interconnected in unknown and possibly time-varying ways, communicate only locally, and are identically programmed. We present a description of this model, and some of the results that have been obtained with it, particularly in the areas of pattern formation and the development of programming languages that are specifically suited to our model. Finally, we briefly describe some of the ongoing efforts in amorphous computing, and we present some of the interesting and important problems that still remain open in amorphous computing.

1222. —. “Towards a Universal Language for Amorphous Computing.” NECSI International Conference on Complex Systems (ICCS 2004). 2004.

We identify several “building-block” activities for the amorphous computing model that can be abstracted and combined in various ways to create interesting patterns of non-local behaviour. We support our discussion by demonstrating how some of the work already done in amorphous computing could have been accomplished through suitable combinations of these building blocks.

<http://www.swiss.ai.mit.edu/projects/amorphous/jsim/sim/GrayScott.html>.

In an amorphous computing environment, myriads of simple computing elements interact locally, under the control of a common program, to produce some prespecified coherent behaviour. The goal of amorphous computing is to find programming paradigms that will enable us to write such programs effectively. We have designed and built an amorphous computing simulator that is capable of simulating 100,000 processors running a small program that involves all processes reachable from a designated starting processor. The simulator is modularised, so that inter-processor communications, controls and outputs are pluggable. The simulator also implements a client-server architecture that allows multiple remote users to collaboratively access a single instance of a simulation.

(Title also in PubMed - A high fidelity tissue-based cardiac surgical simulator for European Journal of Cardiothorac Surgery 27 (2005) 910-916)

Cardiac surgery training in a realistic surgical environment is assisted by a simulator based on an electromechanical pneumatic pump with associated control and display software. In this paper we describe a feedback mechanism for controlling the beating mode of the simulator by means of a electronic pressure sensor incorporated into the pneumatic pump. The sensor was incorporated into an electronic data acquisition board and was used to trigger a ventricular fibrillation (cardiac arrest) mode in the pump control system when the heart attached to the pump is handled by the trainee surgeon, as is typically experienced in a real operation. The mode change also results in changes to simulated vital signs including ECG and pressure traces which are displayed on a monitor within the surgical training environment. Software is described which was designed to drive the pump at various beating rates, display the vital signs, and respond to pressure sensor measurements.

The work described is the continuation of a collaboration between the University Hospital of the West Indies (UHWI), the School of Engineering at the University of Technology, Jamaica (UTech), and the Department of Mathematics & Computer Science at the University of the West Indies (UWI), which has the aim of producing a computer controlled device and training system capable of simulating the range of intra-operative cardiac behaviours typically found in heart surgery, in order to improve training of resident surgeons.

Mugisa .** “Reusable Software Architecture for Intranet Based Accounting Information System.” Proceedings of the Sixth Conference, Faculty of Pure and Applied Sciences: Kingston, Jamaica: Faculty of Pure and Applied Sciences, University of the West Indies, 2003. 32-33.

This work patterns the techniques used in other engineering disciplines in developing complete systems from reusable components. It looks at the development of a reusable blue print or reusable software architecture (RSA) that will guide programmers of software engineers in assembling different systems from reusable components. The benefits of reusability in software systems have been well recognised and are expected to include significant improvement in productivity and increased software quality. Progress in this area is however, still unsatisfactory [Smolárová and Navráť 1997]. There are technical and non-technical reasons hindering reuse technology but the greater successes are observed with the reuse of components that tend to be domain specific and large [Biggerstaff 1997]. Our strategy therefore, is to build on the techniques that have proven to be successful by limiting the study to a specific domain and abstracting away unnecessary smaller sub-component details.

The scope of this work will be limited to the development of a RSA for an intranet based accounting information system (AIS). It involves the development of a RSA that is adaptable to different accounting needs by changing the composition and properties of the architecture. Included in the work is a formal specification of the AIS, an analysis of the RSA; and an appropriate notation for architectural representation.

We consider the system of stochastic differential equations with delay and with nonautonomous nonlinear main part

$$dx_i(t) =$$

$$\sum_{k=1}^n p_{ki}(t) x_{\mu k}$$

$$k(t) + f_i(t, [X]_{t-h})$$

$$dt + i(t, [X]_{t-h})$$

$$dt + w_t,$$

$$i = 1, \dots, n, X(s) = (s), s \in [0, t]. \quad (1)$$

Here $h > 0$, $[X]_{t-h}$

$$X(s) = X(s), \text{ when } s \in [t-h, t], t > h, [X]_{t-h}$$

$$X(s) = (s), \text{ when}$$

$s \in [-1, 0]$, (s) is a given initial process, $X = (x_1, x_2, \dots, x_n)^T$, $\mu_i > 1$ are rational numbers with odd numerators and denominators, w_t is a Wiener process.

For different types of delays in coefficients $f_i(t, [X]_{t-h})$

$$t \text{ and } i(t, [X]_{t-h})$$

t we prove almost sure asymptotic stability of a trivial solution to the system (1) when $(s) \in [0, \infty)$.

Global almost sure asymptotic stability of solutions of some nonlinear stochastic difference equations with cubic-type main part in their drift and diffusive part driven by square-integrable martingale differences is proven under appropriate conditions in R^1 . As an application of this result, the asymptotic stability of stochastic numerical methods, such as partially drift-implicit -methods with variable step sizes for ordinary stochastic differential equations driven by standard Wiener processes, is discussed.

Reports on the results of the S single differential cross section (SDCS) for electron impact ionization of atomic hydrogen at 4.0 eV above threshold using the ‘intermediate energy R-matrix method’ in conjunction with a two-dimensional R-matrix propagation approach. The current approach employs a more densely packed pseudo-state basis and larger interaction volume than in previous close-coupling calculations. Using this, together with different numerical techniques for analysing the SDCS data, provides a greater understanding of the differences that have arisen between previous theoretical studies. The current results are in excellent agreement with recent time-dependent close-coupling and exterior complex scaling calculations.

Designed to provide low cost tracking and navigation services in Jamaica, these services will be possible using the University of the West Indies Cellular Based Error Correction System. The UWI-CBECS System incorporates the Global Positioning System (GPS) [3, 4], a Global Navigation Satellite System which is able to provide position information anywhere on earth. The GPS system by itself cannot provide the accuracy needed, due to uncontrollable factors. The UWI-CBES system will have means to significantly reduce or eliminate the errors introduced by these factors, thus significantly increasing the accuracy of the system. The UWI-CBECS system will require a reliable low cost bidirectional communication network in order to provide the services at low cost.

This paper will introduce a novel multi-node communication network that is built incorporating an existing cellular phone network. A network like this would eliminate the cost of setting up extensive broadcast sites and reduce maintenance and operational cost significantly. When the traffic is high on the network the system is unable to handle a large number of subscribers, thus a number of subscribers will be denied access to the system.

Information and communication technologies have a direct impact on the economic development, and socio-cultural value system of society. The inclusion of satellite aided navigation in transportation is well established worldwide. Air and sea travel has been the main beneficiary of the technique of acquiring accurate position and timing. In recent years, however, satellite navigation has started to expand into other areas such as recreation, security, and emergency response. Within the next five years all marine vessels will be required to have an automatic identification system. It is with this in mind that a project to provide low cost but effective tracking units and service to mariners in Jamaica is being undertaken. The communication programmable microcontroller based processing unit was developed as an alternative solution to more expensive commercial products. The goal of the project is to provide GPS tracking solution for fishing boats and recreational vessels.

In this paper, we present a system called “Information Appliance for Diabetic Patients” which is designed for the monitoring of diabetic patients [1]. The system is an embedded microcomputer that can be used for self or remote

monitoring. IADP is able to store a “Patient profile (PP)”. Each patient profile consists of at least the patient’s name, age, sex, address, weight, occupation, known allergies, medical history and the nearest hospital’s telephone number, doctor’s phone and page numbers. In addition each profile has a database of the patient’s blood sugar, blood pressure, body mass index, periodical urine analysis (protein, glucose, bodies), diet, drug intakes (including dosage quantity and time taken), and exercise periods. IADP also creates schedules for a patient, notifying him as to when his medication should be taken; the required amount is based on factors such as age, weight and daily activities. IADP has the ability to communicate with the external world for remote monitoring using a modem link.

Joyette, W. Mills, L. Alexander, and B. Gleason.** “Recent Changes in Climate Extremes in the Caribbean Region.” Journal of Geophysical Research 107.D21 (2002): 4601. **Refereed**

A January 2001 workshop held in Kingston, Jamaica, brought together scientists and data from around the Caribbean region and made analysis of indices of extremes derived from daily weather observation in the region possible. The results of the analyses indicate that the number of days having very warm maximum or minimum temperatures increased strongly since the late 1950s while the number of days with very cold temperatures decreased. One measure of extreme precipitation shows an increase over this time period while the one analyzed measure of dry conditions, the maximum number of consecutive dry days, is decreasing. These changes generally agree with what is observed in many other parts of the world.

The Micro-tracking System in development at the Physic Department, University of The West Indies is aimed at providing an effective vehicle and asset tracking system which will cover the entire island of Jamaica. The system uses Global Positioning System (GPS) technology in determining location of an asset equipped with a processing unit which was developed by UWI. We aim to improve this system by increasing the accuracy and efficiency of the system and adding navigational capabilities. This is a cost effective GPS error correction system designed to work

with a GSM cellular network. Several factors introduce errors in GPS based positioning calculations. This system is geared towards reducing and/or eliminating these errors and thus increasing the accuracy of the GPS system. This system is able to provide the same services as the Differential GPS (DGPS) systems which are in use today. The DGPS systems use Radio Frequency (RF) transmitters to broadcast error correction information. Our system which uses the existing cellular phone network will eliminate the expensive RF transmitter and the limitations associated with them, thus drastically reducing cost and increasing efficiency significantly. Errors in the pseudorange measurements affect the quality of the GPS solution. These errors can be modeled, and by using DGPS techniques the errors can be removed. Neural Networks and Kalman Filters show much potential in implementing an elegant and efficient solution to the problem. Mapping information and software is needed for both tracking and navigation. The paper is describing implementation of a mapping-software which is able to pin point accurately the GPS receiver position on a digital map. This software will also implement a route planning algorithm, which will be able to generate the “shortest path”, whether shortest time or shortest distance, from point A to point B by considering distance, number of turns, traffic lights, traffic congestion and other dynamic information.

This article describes a contribution to an error evaluation of the GPS Tracking System. Focus of the article is on GPS receiver, satellite in reviews with a dilution of precision and finally on the error of the GPS position projected on the map. Mapping software is an integral part of the GPS Tracking System.

The Caribbean rainfall season runs from May through November and is distinctly bimodal in nature. The bimodality

allows for a convenient division into a early season (May-June-July) and a late season (August-September-October). Evidence suggests that interannual variability in the early season is influenced strongly by anomalies in the sea surface temperatures of the tropical North Atlantic, with positive anomalies over a narrow latitudinal band (0° – 20° N) being associated with enhanced Caribbean rainfall. The coincidence of this band with the main development region for tropical waves suggests a modification of the development of the waves by the warmer tropical Atlantic. The strong influence of the tropical North Atlantic wanes in the late season, with the equatorial Pacific and equatorial Atlantic becoming more significant modulators of interannual variability. The spatial pattern of significant correlation suggests strongly the influence of the El Niño/La Niña phenomenon, with a warm Pacific associated with a depressed late season and vice versa. There additionally seems to be a robust relationship between late season Caribbean rainfall and an east-west gradient of sea surface temperature (SST) between the two equatorial oceanic basins. Oppositely signed SST anomalies in the NINO3 region and the central equatorial Atlantic (0° 15° W, 5° S 5° N) are well correlated with Caribbean Rainfall for this period.

1277. **Taylor, Michael A., and Albert Owino.** “Warm Oceans and Year to Year Variations of Caribbean Rainfall.” Science, Technology and Innovation: UWI Mona Leading the Nation. Mona, Jamaica: University of the West Indies, Mona, 2004. 142-46.

Focuses on climate and its relative impact on life and daily existence in the Caribbean. Focuses on the need to understand the mechanisms which derive the year to year variations of seasonal climate. Hence the use of sea surface temperature (SST) as a modulating device/mechanism is suggested to be applicable for climate predictions, which give sufficient time to enable action to benefit from forecasted scenario.

This paper explores the implementation of an algorithm that correlates coordinates expressed in longitude and latitude with a coordinate system specific to Jamaica. Using available information of the road network the GPS results obtained from a vehicle equipped with a GPS receiver and a GSM modem is corrected to fit on a road segment in the network. The national coordinate of Jamaica, JAD69, was used to project the data. JAD69 is based on a Clarke ellipsoid. However, few GPS receivers are compatible with the JAD69 coordinate system. Therefore a datum shift results and a transformation formula has to be employed to have the two systems agree. The algorithm will incorporate the inaccuracy of the map and the GPS receiver to provide the level of accuracy sufficient to ensure that a vehicle’s detected location will correspond to the digitized representation of the road on which the vehicle is traveling.

1279. —. “The Performance of Map Matching in Vehicle Position Sensing.” IEEE Aerospace Conference, IEEEAC Paper # 1001 Version 7 (2005): 1-9. **Refereed**

Satellite-based positioning systems, such as global positioning system, with the aid of a GIS based digital road network, can be used as the position sensor of a vehicle navigation system. From this integration an efficient and effective navigation system can be developed. By integrating the positioning system with a digital road network, errors undergone by the positioning system can be corrected therefore producing a better estimate of the location of the vehicle. This will help in the navigational functions of the system. This paper develops a general map matching algorithm to overcome the inaccuracies of both the positioning system and the road network system to provide accurate determination of the vehicle’s location, by evaluating a list of candidate road segments on a set of criteria and assigning them a weighting score. The projection of the point onto the selected road segment is also discussed.

Despite extensive efforts by engineers there are errors associated with the positioning sensor system and the spatial road network data. The algorithm takes into account the general degree of inaccuracy of the particular position sensor, the historical path of travel of the vehicle, typological information of the road network and the heading of the vehicle. The paper also examines the criteria that are used in map matching algorithm and the ideal relation between the different criteria and the weighting score of the candidate road segments. The data presented in this paper is as a result of the evaluation of the performance of this algorithm on data gathered from a field test carried out in the urban road network in the major metropolitan area of Kingston, Jamaica.

Information and communication technologies have a direct impact on the economic development, political organization, and socio-cultural value system of a society. The inclusion of satellite aided navigation in transportation is well established worldwide. Air and sea travel has been the main beneficiary of the technique of acquiring accurate position and timing. In recent years, however, satellite navigation has started to expand into other areas such as recreation, security, and emergency response. In fact by the next five years all marine vessels will be required to have an automatic identification system (AIS). It is with this in mind that a project of this nature is currently being carried out to provide low cost but effective tracking units and service to mariners in Jamaica. The communication programmable microcontroller based processing unit was developed as an alternative solution to more expensive commercial products. The goal of the project is to provide GPS tracking solution for fishing boats. The processing unit is equipped with two communication ports one dedicated for the GPS receiver and the second for radio link. One of the main features is a robust self responded programmable mode of operation.

1281. ——. "Preprocessing Communication Unit (PCU) With Short Message Service (SMS) Communication Channels for AVL Tracking." Proceedings of SPIE, Ed. Yilin Zhao. 2003.

The preprocessing GPS - SMA Communication Unit (PCU) is a mobile tracking device used within AVL tracking systems for determining the location of vehicles. It was designed primarily to utilize the SMS service of the GSM network for communicating. The use of SMS messages is part of an effort aimed at providing a cost effective alternative for tracking the location of vehicles. Its primary function is to send information about user location across a GSM network to a Central Base Station (CBS) from which assets are being tracked. Though SMS is the main bearer, the unit is also capable of using Circuit Switch Data Service (CSD) to send and receive data from the Base Station (BS). The PCU was developed as a small hardware unit based on the Microchip microcontroller, with a multiplexer switching two RS 232 serial inputs. One input is dedicated to the GPS receiver and the second one to the wireless modem.

The Pre-Processing GPS-SMS Communication Unit (PCU) was developed as a part of the University of The West Indies (UWI) Micro-Tracking System project. This project is aimed at developing a comprehensive cost effective system for tacking the location of vehicles across Jamaica. The PCU is the mobile Unit component of tracking system. Its primary function is to send information about user location across a GSM network to a Central Base Station from which assets are being tracked. The unit uses GSM Short Message Service (SMS) as the main bearer to communicate with the Base Station. The unit is also capable of using Circuit Switch Data Service CSD to send and receive data from the Base Station. The PCU was developed as a small hardware unit based on the microchip microcontroller, with a multiplexer switching two RS 232 serial inputs. One input is dedicated to the GPS receiver and the second one to the wireless modem.

1284. —. “SMS TCP/IP Interface.” 2003 IEEE Aerospace Conference Proceedings, IEEEAC Paper #1183: March 8-15, 2003Big Sky, Montana: IEEE, 2003.(CD-ROM) **Refereed**

The SMS TCP/IP Interface is a layered software module which provides a structured method for adding short message service (SMS) functionality to Moving Maps Tracking Software. The system uses a TCP/IP connection method to interface with the tracking software. In an Automatic Vehicle Location (AVL) system that uses SMS messages to send tracking data to its Base Station, the SMS TCP/IP interface is responsible for the reception and processing of messages at the BS before passing the data to the tracking software. The interface software also demonstrates an easy structured method for adding new services, functionality, protocols and even hardware to an AVL Systems with minimum changes to the base station arrangement.
