Protective Effects of Liquiritin on the Brain of Rats with Alzheimer’s Disease
X Huang¹,², Y Wang¹, K Ren¹

ABSTRACT

Background: Alzheimer’s disease (AD) is a sort of nerve degenerative disease with clinical manifestation of memory damage and cognitive dysfunction. Its typical pathological change is the abnormal deposition of amyloid-beta (Aβ).

Method: In this study, a rat AD model with liquiritin (LQ) interference was established to observe the effects of LQ on the AD rats’ behavioural memory and primary hippocampus cells.

Results: Liquiritin had the effect of improving the rats’ learning and memory ability, enhancing the activity of catalase (CAT), superoxide dismutase (SOD) and glutathione peroxidase (GSH-Px) in rats’ brain tissues, increasing the antioxidant ability, protecting the primary cultured hippocampal neurons and inhibiting the apoptosis induced by Aβ25–35.

Conclusion: The protective effects of LQ can be related to the enhancement of antioxidase activity and clearance of oxygen radicals.

Keywords: Alzheimer’s disease, β-amyloid peptide, liquiritin, oxygen radicals, primary hippocampal neurons

INTRODUCTION

With the increase of an ageing population across the world, more and more old people are affected by Alzheimer’s disease (AD) to different degrees. As a sort of nerve degenerative disease, AD is clinically manifested by progressive memory damage and cognitive dysfunction (1). Although the etiology of AD is not yet clear, a number of studies have demonstrated that the development of AD is mainly caused by the neuroinflammation induced by the deposition of amyloid-beta (Aβ) which activated the microglia (2). The pathological state of AD patients’ brain tissues is mainly manifested by senile plaque (SP) induced by deposition of β-amyloid peptide (A-
tion of Aβ is the typical one. Amyloid-beta, activating the cholinergic neuron, as well as amyloidosis in cerebral cortex arteries and arterioles, among which the abnormal deposition of Aβ is the typical one. Amyloid-beta, activating the inflammatory reaction of microglia and astrocyte, induces the release of various inflammatory media with neurotoxic effects, resulting in a central lesion (3–5). Therefore, the toxicity of hippocampal neurons is regarded as the principal mechanism of AD.

Chinese herbs used to improve learning memory and prevent senile dementia are natural, multi-effective and usually less toxic than prescribed medications. A number of studies have been done on plant extracts for brain function improvement and senile dementia treatment. Liquorice root, a perennial herb of leguminosae, can be traced back to Shen Nong’s herbs. Recently, the study of liquorice mostly focussed on its chemical composition of more than 300 flavonoids, 60 terpenoids, coumarins, 18 amino acids, various alkaloids, female hormones and organic acids etc in which the active constituents included the compounds of flavonoids, triterpenes and liquorice polysaccharides (6). The active constituent, liquiritin (LQ), has the effects of relieving pain and cough, and preventing inflammation, ulcer and allergic reaction; it also functions as an immunological enhancement, and the pharmacologic action may prevent viral hepatitis, cancer and AIDS (7–10). Liquiritin, belonging to the flavonones, is the potent constituent of Glycyrrhiza uralensis roots, mol fm = C_{21}H_{22}O_{9}, mol wt = 418.13 (11). Researchers have shown that LQ, with various bioactivities, is related to the antioxidant which has been clinically used in cardiovascular diseases, cancers and immune system disorders (12, 13). Due to the progression of pharma-co-activity studies of multidrug resistance, LQ has become one of the natural activity products attracting much attention.

In this study, a rat AD model with LQ interference was established using local injection of Aβ 25–35 into the lateral ventricle, to observe the effects of LQ on the AD rats’ behavioural memory. Meanwhile, a rat primary cultured nerve cell model was set up to study the protective effects of LQ on primary cultured hippocampal cells, with an attempt to verify the effects of LQ on AD and its mechanisms from the perspective of molecular and cellular levels as well as the holzo-zooscopy, and to provide experimental evidence for prevention and treatment of AD.

SUBJECTS AND METHODS

Experimental animal

Forty male SPF Sprague Dawley rats (200 ± 50 g) and neonates (born within 24 hours, 50% male and 50% female) were purchased from the Experimental Animal Breeding Centre, Jilin University (Changchun, Jilin, China).

Chemicals

Liquiritin was purchased from the National Institute for the Control of Pharmaceutical and Biological Products, lot no. 201002 (Beijing, China); Aβ 25–35 was gained from Sigma Co (USA). Superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase (GSH-Px) test kits were obtained from Jiancheng Biotech Co (Nanjing, Jiangsu, China). Iscove’s Modified Dulbecco’s Medium (IMDM) culture media, trypsin and fetal bovine serum were purchased from GIBCO Co (USA). N2, B27 and dissection liquid (15.1 mmol/L glucose, 21.9 mmol/L sucrose, 136.9 mmol/L NaCl, 5.4 mmol/L KCl, 0.7 mmol/L Na2HPO4, 7H2O, 0.2 mmol/L KH2PO4, pH 7.2–7.4) were also obtained from GIBCO Co (USA).

Instrumentation

The UV-vis Spectrophotometer 722 was produced by Xin Mao Instruments Ltd Co (Shanghai). The semi-automatic Biochemical Analyzer GF-D600 was purchased from KaiAo Tech Ltd Co (Beijing). The microplate reader WD-9417A was obtained from Thermo Co (USA). The biosafety cabinet for cell culture was purchased from Biology Apparatus Co (Shanghai). The CO2 incubator for cell culture was produced by Helaeus Co (Germany). The flow cytometer was obtained from Becton Dickinson (USA).

Experimental grouping and preparation of AD rat model

Sprague Dawley rats were randomly divided into five groups of eight rats each (normal control group, AD model group, high-dose LQ group [80 mg/kg], moderate-dose LQ group [40 mg/kg] and low-dose LQ group [20 mg/kg]) who were orally gavaged with corn oil containing LQ for seven days. On the eighth day, after being anesthetized with 2% pentobarbital sodium (40 mg/kg), the rats were fixed to a brain stereotactic apparatus and parietal hairs were cut. After being disinfected with iodine, the cranium was drilled open at a spot which was 1.0 mm posterior to the anterior fontanel, 1.7 mm right to the median and 5 μl Aβ 25–35 (10 mmol/L) was vertically injected into the cerebral dura mater; two minutes later, the microinjector was withdrawn and the incision was sewn up. The intragastric administration lasted for another 14 days (14).

Morris water maze

After the administration, Morris water maze (150 cm × 60 cm × 30 cm) was used in an ethological test according to the previous reports (15–17). The maze was divided into four quadrants with a platform (10 cm) in the centre of quadrant 3. The opaque black water (using black food additive) was 1 cm higher than the platform, without any other changes during the experiment.

Spatial learning test

The Morris water maze test was conducted on each group once a day for five days. On each day, the escape latency of the rats was recorded (no records for over 120 seconds). Rats who failed to find the platform within 120 seconds would be marked as 120 seconds, and forced to memorize the position by
being kept on the platform for 10 seconds. On the 5th day, test for position fixing and space exploration was made to calculate the residence time in quadrant 3 and crossing times of rats in order to check their memory.

**Antioxidative assay**

After the Morris water maze test was finished, all the rats were sacrificed. The rats were sacrificed by cervical dislocation and the brains were dissected and kept in pre-cold Dulbecco’s Modified Eagle Medium (DMEM) basal medium. The brain tissue was rapidly taken out and kept on ice; 400 mg of it was dissolved in saline to prepare the 10% tissue homogenate in an ice bath, and the homogenate was centrifuged at 4000 rpm for 20 minutes to obtain the supernatant. The contents of malondialdehyde (MDA), SOD and GSH-Px in the supernatant were measured according to the instructions of the kits.

**Primary cell culture of hippocampal neurons in rats**

Primary hippocampal neurons were isolated from Sprague Dawley pups within 24 hours after they were born (18, 19). The hippocampus was isolated under a dissecting microscope and kept in pre-cold DMEM basal medium. Afterward, the hippocampus was cut into pieces of 1–3 mm in diameter, digested with 0.125% trypsin, filtered with 200 sieve mesh and centrifuged at 1000 rpm for five minutes to collect the cell pellet. The cell pellet was resuspended with DMEM-F12 + 10% fetal bovine serum and incubated at 37 °C with 5% CO₂. Twenty-four hours later, the medium was replaced with DMEM/F12 + 2% B27. Every three days, half of the medium was changed with new DMEM/F12 + 2% B27. Cells were ready for use after seven days of culture.

**Immunofluorescence assay**

Hippocampal neurons were characterized with B-tubulin III through immunofluorescence assay (20, 21). After seven days of cultivation, primary hippocampal neurons were fixed with 4% paraformaldehyde, permeabilized with 0.3% Triton X-100 and then co-cultured with mouse anti-rat primary antibody (1:100 dilution) overnight at 4 °C. TRITC-labelled anti-mouse secondary antibody was added on the second day after primary antibody was washed out three times with phosphate buffered saline (PBS). After two hours of incubation at room temperature, cells were photographed with a digital camera (AxioCam; Zeiss) coupled to an inverted microscope (AxioVert; Zeiss), using AxioVision 3.1 software (Zeiss).

**MTT assay and LDH level test**

After seven days of cultivation of the hippocampal neurons, 10 µmol/L Aβ25–35 was injected into the model group. Liquiritin groups were given LQ (0.1, 1, 10 µmol/L) and 10 µmol/L Aβ25–35, respectively with an interval of 24 hours. The same volume of saline was given to the control group. Seventy-two hours later, 5 µg/mL MTT was added, and the supernatant was removed after four hours incubation at 37 °C. The reaction was stopped by 150 ul dimethyl sulfoxide (DMSO). Optical density (OD) was measured at 570 nm and the survival rate was calculated (22). Following the instructions of the lactate dehydrogenase (LDH) test kit, culture solution was taken to detect the absorbance at 440 nm and to measure the LDH level (23).

**Apoptosis detection assay**

The hippocampal neurons, cultivated for seven days and induced by Aβ25–35 for 48 hours, were washed by PBS and digested by 0.125% trypsin. The cells were put into 200 µl buffer, after 10 minutes staining with annexin V-FITC/PI (24), to be detected by flow cytometer in order to calculate the apoptosis ratio.

**Statistical analysis**

All experiments were repeated at least three times (mean ± SEM). Significance (p < 0.05) was determined by either a one-way or two-way analysis of variance (ANOVA) with a post hoc mean comparison performed by Newman Keuls multiple range test. A Student’s t-test was used when the means of the two groups were compared.

**RESULTS**

**Spatial learning and memory test**

Compared with those in the model group, the escape latency of the LQ group (40 and 80 mg/kg·d) was significantly shortened, and crossing times and residence time in quadrant 3 were increased (p < 0.05, p < 0.01) [Table 1]. The results suggest that LQ may improve the rats’ spatial learning and memory ability.

* p < 0.05, ** p < 0.01 vs control group; *p < 0.05, **p < 0.01 vs model group

**Antioxidative assay**

As shown in Table 2, compared with those in the model group, CAT and SOD contents of rats’ brain tissues in the LQ groups were increased, and CAT, SOD and GSH-Px activity in the LQ groups (40 and 80 mg/kg·d) was higher statistically (p < 0.05, p < 0.01).

After seven-day culture with non-serum nerve solution, the original round hippocampal neurons were interlaced like a net with many projections, the cells of which grew into the typical fusiform and cone shape. Microscopically, these cells were positively stained with the heterologous protein β-tubulin III (Fig. 1), which determined the neuron cells.
Protection of hippocampal neurons by LQ
According to MTT test, compared with that in the model group, OD in LQ (1 µmol/mL, 10 µmol/mL) was statistically significantly higher \((p < 0.05)\), which indicated that LQ may reduce the injury induced by Aβ\textsubscript{25–35}. The LDH test showed that LDH activity in the supernatant of LQ (1 µmol/mL, 10 µmol/mL) was significantly lower statistically \((p < 0.05)\) as compared with that in the model group, which suggested that LQ has positive effects on the reduction of injuries of primary hippocampal neurons (Fig. 2).

Inhibitory effect of LQ on apoptosis of hippocampal neurons
Compared with that in the model group, the cell distribution of apoptosis was gradually decreased in the LQ group (1 µmol/mL, 10 µmol/mL), with the apoptosis percentage as 15.37 ± 1.60% and 14.30 ± 1.78%, which was statistically significant \((p < 0.01, p < 0.01)\) [Fig. 3]. This implied that the apoptosis of hippocampal neurons induced by Aβ\textsubscript{25–35} was inhibited by LQ.

**DISCUSSION**
Amyloid beta, as the essential component for the cerebral pathological feature senile plaque of AD patients (25), showed great neurotoxicity and induced apoptosis through various ways, such as oxidative stress (26). In our study, an AD model was made by injecting Aβ\textsubscript{25–35} and deposition of Aβ. The spatial learning memory of rats was tested by the Morris water maze test. The model in this study simulated the ethological effects of AD learning and memory disorders. According to the Morris test, the escape latency of rats in the Aβ group was longer than that in the control group. Liquiritin has the effects of reducing the escape latency of AD rats and increasing the crossing times and residence time in quadrant 3, which indicated that the learning memory ability of AD rats could be improved by LQ and implied favourable therapeutic action of LQ on AD. With the intervention of LQ, the activity of CAT, SOD and GSH-Px in brain tissues of AD rats was significantly increased, which demonstrated the effects of SOD on clearance of free radicals and function of injuries (27). The excess peroxide and the free radicals were cleared, respectively by CAT in peroxisome (28, 29) and GSH-Px in mitochondria (30). The results in our study suggested that LQ was effective in increasing the activity of CAT, SOD, GSH-Px, clearing the free radicals and protecting the oxidative damage induced by Aβ.
In this study, \( \text{A}\beta_{25-35} \) was applied to the primary hippocampal neurons to simulate the prophase pathological process of AD (31). MTT assay and LDH level test showed the metabolic activity and cell integrity (32, 33). The results indicated the protective effects of LQ on nerve cells since MTT value was increased by LQ and LDH level was decreased by it. The inhibitive effects of LQ on the apoptosis of nerve cells induced by \( \text{A}\beta_{25-35} \), which were tested by annexin V-FITC/PI FCM, can be one of the protective mechanisms of LQ on neurons.
